#### Abstract

We establish the conjugacy of Cartan subalgebras for generic Lie tori "of type A". This is the only conjugacy problem of Lie tori related to Extended Affine Lie Algebras that remained open.

## Introduction

Extended Affine Lie Algebras (EALAs for short) are a rich class of Lie algebras that were first conceived by the physicists R. Høegh-Krohn and B. Torresani and

[^0]then brought to the attention of mathematicians by P. Slodowy (the reader should look at $[\mathrm{Ne} 2]$ and $[\mathrm{Ne} 3]$ for a comprehensive review of basic EALA theory and references. The original mathematical formulation is to be found in [AABGP]). An EALA has an invariant non-negative integer attached called its nullity. In nullity 0 EALAs are nothing but the finite-dimensional simple Lie algebras, while in nullity 1 EALAs are the celebrated affine Kac-Moody Lie algebras (we assume for simplicity in this Introduction that our base field is the complex numbers). Roughly speaking an EALA $E$ is constructed from a class of Lie algebras called Lie tori by taking a central extension and adding a suitable space of derivations. In the case of the affine algebras, for example, the Lie torus is a loop algebra $L$ based on a finite-dimensional simple Lie algebra $\mathfrak{g}$. Note that $L$ is naturally a Lie algebra over the Laurent polynomial ring $\mathbb{C}\left[t^{ \pm 1}\right]$ ). This ring is the centroid of $L$.The central extension of $L$ is the universal one (which is one-dimensional). The space of derivations is also one-dimensional and corresponds to the degree derivation $t(d / d t)$.

An EALA, by definition, comes equipped with a so-called Cartan subalgebra (just like the affine algebras do, but unlike the finite-dimensional simple Lie algebras; see $\S 2$ for details). In the setting of EALAs, a Cartan subalgebra is the same as a self-centralizing ad-diagonalizable subalgebra, as defined in $\S 2.7$. With respect to the given Cartan subalgebra the EALA admits a root space decomposition. The structure of the resulting "root system" plays a fundamental role in understanding the structure as well as the representation theory of the given EALA. It is obvious that all of this would be of little use (or mathematically unnatural) if the nature of the root system was to depend on the choice of Cartan subalgebra. The most elegant way of dealing with this problem is by establishing "Conjugacy", i.e., by showing that all Cartan subalgebras are conjugate under the action of the group of automorphisms of the EALA (in all cases it is sufficient to use a precise subgroup of the full group of automorphisms. Conjugacy in the finite-dimensional case, in the spirit of the present work, is due to Chevalley. For the affine algebras the result is due to Peterson and Kac [PK]). For almost all EALAs (see below) conjugacy, hence the invariance of the root system, has been established in [CGP] (for Lie tori) and [CNPY] (for the full EALAs). One case, the so called non-fgc case (see $\S 2$ for definitions), remained open. The purpose of this paper is to establish conjugacy for the Lie tori (the analogue of [CGP] in the non-fgc case) underlying this remaining family of EALAs.

The centroid of a Lie torus $L$ is always a Laurent polynomial ring $R$ in finitely many variables. In all cases but one, $L$ is an $R$-module of finite type. This is the fgc case (where fgc stands for finitely generated over the centroid). When this does not happen, the non-fgc case, the nature of $L$ is perfectly understood:

$$
L=\mathfrak{s l}_{\ell}(Q)
$$

where $Q$ is a quantum torus with at least one generic entry. We remind the reader that by definition $Q$ is the complex unital associative algebra presented by generators $x_{1}, \ldots, x_{n}, x_{1}^{-1}, \ldots, x_{n}^{-1}$ and relations

$$
x_{i} x_{i}^{-1}=1_{Q}=x_{i}^{-1} x_{i}, \quad x_{i} x_{j}=q_{i j} x_{j} x_{i},
$$

where the $q_{i j}$ are non-zero complex numbers. That "one entry be generic" means that one of the $q_{i j}$ cannot be a root of unity. The centre $\mathcal{Z}(Q)$ of $Q$ is always a Laurent polynomial ring. The fgc condition on the Lie algebra $\mathfrak{s l}_{\ell}(Q)$ is equivalent to $Q$ being a $\mathcal{Z}(Q)$-module of finite type.

We can now state our
Main Theorem. Let $f: \mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right) \rightarrow \mathfrak{s l}_{\ell}(Q)$ be an isomorphism of non-fgc Lie tori. Then $\ell=\ell^{\prime}$ and if $\mathfrak{h}^{\prime}$ and $\mathfrak{h}$ denote the given Cartan subalgebras of $\mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)$ and $\mathfrak{s l}_{\ell}(Q)$ respectively, ${ }^{2}$ then $f\left(\mathfrak{h}^{\prime}\right)$ and $\mathfrak{h}$ are conjugate under an automorphism of $\mathfrak{s l}_{\ell}(Q)$.

In the fgc case the proof of conjugacy is naturally divided into two steps. One first establishes conjugacy at the level of Lie tori, and then extends this conjugacy "downstairs" to the full EALA. The fgc condition allows the Lie tori to be viewed as simple Lie algebras (in the sense of [SGA3]) over Laurent polynomial rings. Conjugacy in the fgc case makes heavy use of the powerful methods of [SGA3] and Bruhat-Tits theory. None of this is possible in the non-fgc case. New methods/ideas are needed. The crucial ingredient that we develop to deal with this new situation is a method that we call "specialization". The idea, roughly speaking, is to create a subring $R$ of $\mathbb{C}$ with the property that
(i) our non-fgc Lie torus "exists" over $R$,
(ii) there exists a maximal ideal $\mathfrak{m}$ of $R$ which after base change (reduction modulo $\mathfrak{m}$ ) yields an fgc Lie torus.
The catch is that the field $R / \mathfrak{m}$ is of positive characteristic! One does not even have a suitable definition of Lie tori in positive characteristic. Yet the resulting object and its group of automorphisms is explicit enough that we can establish conjugacy for them. The specialization method is invoked once again to show that conjugacy holds before the reduction modulo $m$.

Notation. Throughout, $R$ is a commutative unital ring which often occurs as the base ring of some algebraic structure being considered; $F$ is an arbitrary field, and $k$ often denotes a field of characteristic 0 . An $R$-algebra is an arbitrary algebra over $R$ (in particular not necessarily associative or a Lie algebra). Group schemes are usually denoted with bold letters. For example, $\mathbf{P G L} L_{m, R}$ denotes the $R$-group scheme of automorphisms of the (associative and unital) $R$-algebra $M_{m}(R)$.

Structure of the paper. In Section 1 we collect some basic results about centroids of (arbitrary) algebras. Particular attention is devoted to the case of quantum tori. Section 2 looks at the structure of the Lie algebra $\mathfrak{s l}_{\ell}(Q)$ where $Q$ is a quantum torus. The definition and basic properties of maximal abelian diagonalizable (MAD) subalgebra are also given in this section (these are the subalgebras that play the role of the Cartan subalgebras in EALA theory). Section 3 is devoted to a detailed study of the group scheme $\mathbf{P G} \mathbf{L}_{\mathcal{A}}$ where $\mathcal{A}$ is an Azumaya algebra over a ring $R$, and of the connection between this $R$-group scheme and the $R$-group scheme of automorphisms of $\mathfrak{s l}_{\ell}(\mathcal{A})$. Section 4 presents a detailed analysis of the

[^1]automorphism group of the Lie algebra $\mathfrak{s l}_{\ell}(Q)$ when $Q$ is an fgc quantum torus. Section 5 develops the method that we called "specialization" mentioned above. This is the key that allows us to deal with the non-fgc case by translating the problem into an fgc question, but now over fields of positive characteristic. Section 6 presents a collection of preliminary results to be used in the proof of the main Theorem, which is given in Section 7.

## 1. Some results on centroids and quantum tori

### 1.1. Centroids and base change

Let $R$ be a commutative ring and let $\mathcal{A}$ be an arbitrary $R$-algebra. ${ }^{3}$ Recall that the derived subalgebra of $\mathcal{A}$ is the additive subgroup of $\mathcal{A}$ generated by all products $a b$ with $a, b \in \mathcal{A}$. It is trivial to see that this group is indeed an $R$-subalgebra of $\mathcal{A}$. The algebra $\mathcal{A}$ is called perfect if it equals to its derived algebra. Note that any unital algebra is perfect.

A crucial object for our work is the centroid $\operatorname{Ctd}(\mathcal{A})$ of the algebra $\mathcal{A}$. Recall that

$$
\operatorname{Ctd}(\mathcal{A})=\left\{\chi \in \operatorname{End}_{R}(\mathcal{A}): \chi\left(a_{1} a_{2}\right)=\chi\left(a_{1}\right) a_{2}=a_{1} \chi\left(a_{2}\right) \text { for all } a_{i} \in \mathcal{A}\right\}
$$

Clearly $\operatorname{Ctd}(\mathcal{A})$ a unital commutative (if $\mathcal{A}$ is perfect) subalgebra of the associative $R$-algebra $\operatorname{End}_{R}(\mathcal{A})$. It is obvious that we can consider $\mathcal{A}$ as an algebra over $\mathcal{C}=\operatorname{Ctd}(\mathcal{A})$ - it will be denoted $\mathcal{A}_{(\mathcal{C})}{ }^{4}$ We will say that $\mathcal{A}$ is fgc if $\mathcal{A}_{(\mathcal{C})}$ is a finitely generated $\mathcal{C}$-module.

More generally, if $S \in R$-alg, i.e., $S$ is a unital associative commutative $R$ algebra, and if $\rho: S \rightarrow \operatorname{Ctd}(\mathcal{A})$ is a unital algebra homomorphism, $\mathcal{A}$ becomes an $S$-algebra by defining $s \cdot a=\rho(s)(a)$ for $s \in S$ and $a \in \mathcal{A}$. We will denote the algebra obtained in this way by $\mathcal{A}_{(\rho)}$ or $\mathcal{A}_{(S)}$ if $\rho$ is clear from the context.

Example 1. Assume that $f: \mathcal{A}^{\prime} \xrightarrow{\sim} \mathcal{A}$ is an isomorphism of perfect $R$-algebras. It is then easily seen (and well known) that

$$
\begin{equation*}
\operatorname{Ctd}(f): \operatorname{Ctd}(\mathcal{A}) \xrightarrow{\sim} \operatorname{Ctd}\left(\mathcal{A}^{\prime}\right), \quad \chi \mapsto f^{-1} \circ \chi \circ f \tag{1.1.1}
\end{equation*}
$$

is an isomorphism of $R$-algebras. Since $\mathcal{C}=\operatorname{Ctd}(\mathcal{A}) \in R$-alg, we can use $\operatorname{Ctd}(f)$ to make $\mathcal{A}^{\prime}$ a $\mathcal{C}$-algebra: $\chi \cdot a^{\prime}=(\operatorname{Ctd}(f)(\chi))\left(a^{\prime}\right)=\left(f^{-1} \circ \chi \circ f\right)\left(a^{\prime}\right)$. Then

$$
\begin{equation*}
f: \mathcal{A}_{(\mathcal{C})}^{\prime} \rightarrow \mathcal{A}_{(\mathcal{C})} \text { is } \mathcal{C} \text {-linear. } \tag{1.1.2}
\end{equation*}
$$

Indeed,

$$
f\left(\chi \cdot a^{\prime}\right)=f\left(\left(f^{-1} \circ \chi \circ f\right)\left(a^{\prime}\right)\right)=\chi\left(f\left(a^{\prime}\right)\right)=\chi \cdot f\left(a^{\prime}\right)
$$

for $\chi \in \mathcal{C}$ and $a^{\prime} \in \mathcal{A}^{\prime}$.
Example 2 (centre). Let $\mathcal{A}$ be a unital associative $R$-algebra. As usual, $[a, b]=$ $a b-b a$ for $a, b, \in \mathcal{A}$ denotes the (Lie) commutator. The centre $\mathcal{Z}(\mathcal{A})=\mathcal{Z}$ consists

[^2]of all $z \in \mathcal{A}$ satisfying $[z, a]=0$. One easily checks that the left multiplication by a central element is an isomorphism of $R$-algebras:
\[

$$
\begin{equation*}
\mathcal{Z}(\mathcal{A}) \xrightarrow{\sim} \operatorname{Ctd}(\mathcal{A}), \quad z \mapsto L_{z} . \tag{1.1.3}
\end{equation*}
$$

\]

Hence we can (and will) consider $\mathcal{A}$ as a $\mathcal{Z}$-algebra, denoted $\mathcal{A}_{(\mathcal{Z})}$.
Example 3. Let $\mathcal{A}$ be as above and let $\mathcal{L}=\mathfrak{s l}_{\ell}(\mathcal{A})$ be the special linear Lie $R$-algebra introduced in 2.2 . If $\mathcal{Z}=\mathcal{Z}(\mathcal{A})$, we have an obvious $R$-algebra homomorphism

$$
\zeta: \mathcal{Z} \rightarrow \operatorname{Ctd}(\mathcal{L}), \quad \zeta(z)=\left(\left(x_{i j}\right) \mapsto\left(z x_{i j}\right)\right)
$$

for $z \in \mathcal{Z}$ and $x=\left(x_{i j}\right) \in \mathcal{L}$. We will show in Lemma 2.4 that $\zeta$ is an isomorphism if $\ell \geq 2$ and $\frac{1}{2} \in R$. It is easily seen that

$$
\begin{equation*}
\mathfrak{s l}_{\ell}(\mathcal{A})_{(\mathcal{Z})}=\mathfrak{s l}_{\ell}\left(\mathcal{A}_{(\mathcal{Z})}\right) \tag{1.1.4}
\end{equation*}
$$

### 1.2. Some properties of quantum tori

We list some properties of quantum tori that we will use. Throughout, $F$ is a field of arbitrary characteristic, and $\Lambda$ is a free abelian group of rank $n$.
(a) (Definitions) By definition, a quantum torus (with grading group $\Lambda$ ) is an associative unital $\Lambda$-graded $F$-algebra $Q=\bigoplus_{\lambda \in \Lambda} Q^{\lambda}$ such that $\operatorname{dim} Q^{\lambda}=1$ for all $\lambda \in \Lambda$ and that every $0 \neq a \in Q^{\lambda}$ is invertible.

After fixing a basis $\boldsymbol{\varepsilon}=\left(\varepsilon_{i}\right)$ of $\Lambda$, we can choose $0 \neq x_{i} \in Q^{\varepsilon_{i}}$ and then get a quantum matrix $q=\left(q_{i j}\right) \in \mathrm{M}_{n}(F)$ defined by $x_{i} x_{j}=q_{i j} x_{j} x_{i}$. Then, using $x_{i}^{-1}=$ the inverse of $x_{i}$, we define $x^{\lambda}=x_{1}^{\ell_{1}} \cdots x_{n}^{\ell_{n}}$ for $\lambda=\ell_{1} \varepsilon_{1}+\cdots+\ell_{n} \varepsilon_{n} \in \Lambda$ :

$$
\begin{equation*}
Q=\bigoplus_{\lambda \in \Lambda} F x^{\lambda} \tag{1.2.1}
\end{equation*}
$$

One can then also realize a quantum torus as the unital associative $F$-algebra presented by generators $x_{1}, \ldots, x_{n}, x_{1}^{-1}, \ldots, x_{n}^{-1}$ and relations

$$
x_{i} x_{i}^{-1}=1_{Q}=x_{i}^{-1} x_{i}, \quad x_{i} x_{j}=q_{i j} x_{j} x_{i} .
$$

We will refer to this view of $Q$ as a coordinatization.
We point out that such a presentation is not unique: it depends on the chosen $\mathbb{Z}$-basis $\varepsilon$ of $\Lambda$. In other words, for any integral matrix $A=\left(a_{i j}\right) \in \mathrm{GL}_{n}(\mathbb{Z})$ the set $\tilde{x}=\left\{\tilde{x}_{1}, \ldots, \tilde{x}_{n}\right\}$ of invertible elements in $Q$, defined by

$$
\tilde{x}_{1}=x_{1}^{a_{11}} \cdots x_{n}^{a_{1 n}}, \ldots, \tilde{x}_{n}=x_{1}^{a_{n 1}} \cdots x_{n}^{a_{n n}}
$$

also generates $Q$ and the associated quantum matrix $\tilde{q}=\left(\tilde{g}_{i j}\right)$ is given by $\tilde{q}_{i j}=$ $\prod_{s, t} q_{s t}^{a_{i s} a_{j t}}$.
(b) The centre of $Q$ is a $\Lambda$-graded subalgebra,

$$
\mathcal{Z}(Q)=\bigoplus_{\xi \in \Xi} Q^{\xi}
$$

where $\Xi$ is the so-called central grading group:

$$
\Xi=\left\{\lambda \in \Lambda: Q^{\lambda} \subset \mathcal{Z}(Q)\right\} .
$$

This is a free abelian group of rank $z \leq n$. Hence $\mathcal{Z}(Q)$ is a Laurent polynomial ring in $z$ variables, which we may take as $t_{1}, \ldots, t_{z}$ (these can be taken to be of the form $x^{\lambda}$ for suitable $\lambda \mathrm{s}$ ).
(c) We define

$$
[Q, Q]=\operatorname{span}_{F}\{[a, b]: a, b \in Q\},
$$

a graded subspace of $Q$. One knows (see, e.g., [BGK, Prop. 2.44(iii)] for $F=\mathbb{C}$ or [NY, (3.3.2)] in general)

$$
\begin{equation*}
Q=\mathcal{Z}(Q) \oplus[Q, Q] . \tag{1.2.2}
\end{equation*}
$$

(d) $Q$ is a domain: $a b=0$ for $a, b \in Q$ implies that $a=0$ or $b=0$, whence a nondegenerate and thus prime associative $F$-algebra. This implies that $Q$ is connected: the only idempotents in $Q$ are 0 and $1_{Q}$.
(e) An element $u$ of $Q$ is invertible if and only if $0 \neq u \in Q^{\lambda}$ for some $\lambda \in \Lambda$.
(f) The grading properties of a quantum torus $Q$ show that $Q$ is fgc in the sense of 1.1 if and only if $\Xi$ has finite index in $\Lambda$. Equivalently, for some (hence all) coordinatization all entries $q_{i j}$ of the quantum matrix $q$ have finite order. If this holds, then for every coordinatization the $q_{i j}$ have finite order.
(g) We let $\mathcal{Z}=\mathcal{Z}(Q)$, and denote by $\widetilde{\mathcal{Z}}$ the quotient field of $\mathcal{Z}$, a rational function field. The $\widetilde{\mathcal{Z}}$-algebra

$$
\widetilde{Q}=Q \otimes_{\mathcal{Z}} \widetilde{\mathcal{Z}}
$$

is called the central closure of $Q$. It has the following properties: $\widetilde{Q}$ is a central $\widetilde{\mathcal{Z}}$ algebra, $\widetilde{Q}$ is a domain (since $Q$ is a domain), and $Q$ embeds into $\widetilde{Q}$. In particular, if $Q$ is fgc, then $\widetilde{Q}$ is a finite-dimensional central domain over $\widetilde{\mathcal{Z}}$, whence a central division $\widetilde{\mathcal{Z}}$-algebra.
(h) (Trace, $\mathbb{Z}$-grading, degree) As in (a) we fix a basis $\varepsilon=\left(\varepsilon_{1}, \ldots, \varepsilon_{n}\right)$ of $\Lambda$ and define the $\boldsymbol{\varepsilon}$-trace as $\operatorname{tr}_{\boldsymbol{\varepsilon}}(\lambda)=\sum_{i} \lambda_{i}$ for $\lambda=\sum_{i} \lambda_{i} \varepsilon_{i}$ with $\lambda_{i} \in \mathbb{Z}$. Since $\operatorname{tr}_{\boldsymbol{\varepsilon}}: \Lambda \rightarrow \mathbb{Z}$ is a group homomorphism, the $\Lambda$-grading of $Q$ can be made into a $\mathbb{Z}$-grading

$$
\begin{equation*}
Q=\bigoplus_{n \in \mathbb{Z}} Q_{(n, \varepsilon)} \quad \text { with } \quad Q_{(n, \varepsilon)}=\bigoplus_{\operatorname{tr}_{\varepsilon}(\lambda)=n} Q^{\lambda} . \tag{1.2.3}
\end{equation*}
$$

Every $0 \neq q \in Q$ can be uniquely written as $q=\sum_{n \leq m} q_{(n)}$ with $q_{(n)} \in Q_{(n, \boldsymbol{\varepsilon})}$ and $q_{(m)} \neq 0$. We call $m$ the $\varepsilon$-degree of $q$ and denote it by $\operatorname{deg}_{\varepsilon} q$. We put $\operatorname{deg}_{\varepsilon} 0=-\infty$.

In the following we may suppress the dependance on $\varepsilon$ and just speak of the trace. Analogously for the $\mathbb{Z}$-grading (1.2.3).
1.3. Lemma. Let $Q$ be a quantum torus over the field $F$, and let $q, q_{1}, q_{2} \in Q$.
(a) For any $\mathbb{Z}$-basis $\boldsymbol{\varepsilon}$ of $\Lambda$ we have

$$
\begin{align*}
\operatorname{deg}_{\varepsilon}\left(q_{1}+q_{2}\right) & \leq \max \left\{\operatorname{deg}_{\varepsilon}\left(q_{1}\right), \operatorname{deg}_{\varepsilon}\left(q_{2}\right)\right\},  \tag{1.3.1}\\
\operatorname{deg}_{\varepsilon}(s q) & =\operatorname{deg}_{\varepsilon}(q) \quad \text { for } 0 \neq s \in F,  \tag{1.3.2}\\
\operatorname{deg}_{\varepsilon}\left(q_{1} q_{2}\right) & =\operatorname{deg}_{\varepsilon}\left(q_{1}\right)+\operatorname{deg}_{\varepsilon}\left(q_{2}\right) \tag{1.3.3}
\end{align*}
$$

with the obvious rules in case one of $q, q_{1}$ or $q_{2}=0$.
(b) For $0 \neq q \in Q$ we have $q \in Q^{0}=F 1_{Q} \Longleftrightarrow \operatorname{deg}_{\varepsilon}(q)=0$ for all $\mathbb{Z}$-bases $\varepsilon$ of $\Lambda$.

Proof. (a) All formulas are easily verified in case one of $q, q_{1}$ or $q_{2}=0$ (using the convenience that 0 is of degree $-\infty$ ). Also, (1.3.1) and (1.3.2) follow immediately from the definition. For (1.3.3) and $q_{1}, q_{2} \neq 0$ we have $q_{1} q_{2} \neq 0$ since $Q$ is a domain. We write $q_{1}=\sum_{n \leq m} q_{(n)}$ with $\operatorname{deg}_{\varepsilon} q_{1}=m$ and $q_{2}=\sum_{n \leq p} q_{(n)}^{\prime}$ with $\operatorname{deg}_{\varepsilon}\left(q_{2}\right)=p$. Since $Q=\bigoplus_{n \in \mathbb{Z}} Q_{(n, \boldsymbol{\varepsilon})}$ is a $\mathbb{Z}$-grading, it follows that $q_{1} q_{2}=q_{(m)} q_{(p)}^{\prime}+$ terms of lower degree in the $\mathbb{Z}$-grading with respect to $\varepsilon$.
(b) Let $0 \neq q \in Q$. If $q \in Q^{0}$ then $\operatorname{deg}_{\varepsilon}(q)=0$ because $\operatorname{tr}_{\varepsilon}(q)=0$ for any $\mathbb{Z}$-basis $\varepsilon$ of $\Lambda$. Conversely, we can assume $q \neq 0$ and write $q=\sum_{\lambda \in \operatorname{supp}(q)} q^{\lambda}$ with $q^{\lambda} \in Q^{\lambda}$ and $\operatorname{supp}(q)=\left\{\lambda \in \Lambda: q^{\lambda} \neq 0\right\}$. Then $\operatorname{tr}_{\varepsilon}(\lambda) \leq 0$ for every $\lambda \in \operatorname{supp}(q)$ by assumption. But since both $\varepsilon$ and $-\varepsilon$ are $\mathbb{Z}$-bases of $\Lambda$ and $\operatorname{tr}_{-\varepsilon}=-\operatorname{tr}_{\varepsilon}$ we get $\operatorname{tr}_{\boldsymbol{\varepsilon}}(\lambda)=0$ for every $\lambda \in \operatorname{supp}(q)$. For a fixed $\varepsilon$ and $\lambda=$ $\sum_{i=1}^{n} \ell_{i} \varepsilon_{i} \in \operatorname{supp}(q)$ we therefore have $\sum_{i=1}^{n} \ell_{i}=0$. Our claim obviously holds if $\Lambda \cong \mathbb{Z}$. Thus we can assume that $\Lambda$ has rank at least 2 . With respect to the $\mathbb{Z}$-basis $\varepsilon^{\prime}=\left(\varepsilon_{1}+2 \varepsilon_{2}, \varepsilon_{2}, \varepsilon_{3}, \ldots\right)$ we have $\lambda=\ell_{1}\left(\varepsilon_{1}+2 \varepsilon_{2}\right)+\left(\ell_{2}-2 \ell_{1}\right) \varepsilon_{2}+\cdots$. Thus $0=\sum_{i} \ell_{i}=\ell_{1}+\left(\ell_{2}-2 \ell_{1}\right)+\sum_{i \geq 3} \ell_{i}=0$, and $\ell_{1}=0$ follows. Similarly, all $\ell_{i}=0$, i.e., $\lambda=0$.

In the following lemma we will describe certain $F$-diagonalizable endomorphisms $\phi$ of a quantum torus $Q$ over $F$. The term $F$-diagonalizable means of course that there exists an $F$-basis of the $F$-vector space $Q$ consisting of eigenvectors of $\phi$ with eigenvalues in $F$.
1.4. Lemma. Let $Q=\bigoplus_{\lambda \in \Lambda} Q^{\lambda}$ be a quantum torus over the field $F$, and let $d \in Q$.
(a) If $d q=\omega q$ for some $0 \neq q \in Q$ and $\omega \in F$, then $d \in Q^{0}$. In particular, the left multiplication $L_{d}$ for $d \in Q$ is $F$-diagonalizable if and only if $d \in F 1_{Q}=Q^{0}$.
(b) If $[d, q]=\omega q$ for some $0 \neq \omega \in F$, then $q=0$. In particular, the endomorphism $\operatorname{ad} d \in \operatorname{End}_{F}(Q)$, defined by $(\operatorname{ad} d)(q)=[d, q]$, is $F$-diagonalizable if and only if $d \in \mathcal{Z}(Q)$.

Proof. (a) follows from the fact that $Q$ is a domain and $q \neq 0$.
(b) Suppose $0 \neq q$. Then for any $\mathbb{Z}$-basis $\varepsilon$ of $\Lambda$ we get, using the formulas of Lemma 1.3(a),

$$
\begin{aligned}
\operatorname{deg}_{\varepsilon}(d q) & =\operatorname{deg}_{\varepsilon}(d)+\operatorname{deg}_{\varepsilon}(q)=\operatorname{deg}_{\varepsilon}(d)+\operatorname{deg}_{\varepsilon}(-q)=\operatorname{deg}_{\varepsilon}(-q d), \\
\operatorname{deg}_{\varepsilon}(q) & =\operatorname{deg}_{\varepsilon}(\omega q)=\operatorname{deg}_{\varepsilon}(d q-q d) \leq \max \left\{\operatorname{deg}_{\varepsilon}(d q), \operatorname{deg}_{\varepsilon}(-q d)\right\} \\
& =\operatorname{deg}_{\varepsilon}(d q)=\operatorname{deg}_{\varepsilon}(d)+\operatorname{deg}_{\varepsilon}(q)
\end{aligned}
$$

whence $\operatorname{deg}_{\varepsilon}(d) \geq 0$. But since $-\varepsilon$ is also a basis of $\Lambda$, we in fact have $\operatorname{deg}_{\varepsilon}(d)=0$. Thus, by Lemma $1.3(\mathrm{~b})$, we have $d \in Q^{0}$. But then $[d, q]=0$ yields a contradiction. This shows $q=0$, and also that ad $d$ does not have a non-zero eigenvalue. In particular, if ad $d$ is $F$-diagonalizable, necessarily ad $d=0$, i.e., $d \in \mathcal{Z}(Q)$.

In the remainder of this section we present some results which are special for fgc quantum tori.

### 1.5. Canonical presentation

Let $Q$ be a quantum torus over the field $F$, coordinatized as $Q=\bigoplus_{\lambda \in \Lambda} F x^{\lambda}$ as in (1.2.1), and let $q=\left(q_{i j}\right)$ be the associated quantum matrix. We will say that the
coordinatization (or presentation) is canonical if all entries of the quantum matrix $q$ outside of its diagonal blocks of size $2 \times 2$ are equal to 1 . Equivalently, for every $i \geq 1$ the generators $x_{2 i-1}, x_{2 i}$ of $Q$ commute with all other generators $x_{j}$ where $j \neq 2 i-1,2 i$.

The following lemma is stated without proof in [CP, Rem. 7.2]. A proof is given in [Nee, Thm. 4.5].
1.6. Lemma. Any fgc quantum torus $Q$ has a canonical presentation.
1.7. Example (Quantum 2-tori). Let $Q$ be a quantum torus whose grading group has rank 2 . Hence $Q$ is generated by two elements, say $x_{1}, x_{2}$, and the corresponding quantum matrix has the form

$$
q=\left(\begin{array}{cc}
1 & q_{12} \\
q_{12}^{-1} & 1
\end{array}\right)
$$

where $q_{12} \in F^{\times}$. By definition, this presentation of $Q$ is canonical. The algebra $Q$ is fgc if and only if $q_{12}$ is a root of unity, say primitive of degree $\ell$. Let us assume this in the following. The $\mathcal{Z}$-algebra $Q_{(\mathcal{Z})}$ will be called a symbol algebra of degree $\ell$. Its centre $\mathcal{Z}$ is a Laurent polynomial ring (1.2(b))

$$
\mathcal{Z}=k\left[t_{1}^{ \pm 1}, t_{2}^{ \pm 1}\right]
$$

where $t_{1}=x_{1}^{\ell}, t_{2}=x_{2}^{\ell}$ (observe that $\ell$ is independent of the coordinatization, since $\Lambda / \Xi=\ell^{2}$ ). We will usually denote this $\mathcal{Z}$-algebra by $\left(t_{1}, t_{2}\right)_{\mathcal{Z}, q_{12}}$ or simply $\left(t_{1}, t_{2}\right)$ if there is no risk of confusion. Note that $Q_{(\mathcal{Z})}$ has order $\ell$ in the Brauer group $\operatorname{Br}(\mathcal{Z})$.

If $\ell \in F^{\times}$the subalgebra $E=\mathcal{Z}\left[x_{1}^{ \pm 1}\right]$ is a maximal (abelian) étale subalgebra of $Q_{(\mathcal{Z})}$.
1.8. Example. Let $Q=\bigoplus_{\lambda \in \Lambda} F x^{\lambda}$ be an fgc quantum torus over a field $F$. By Lemma 1.6 we can assume that $Q$ is canonically presented, say with quantum matrix $q=\left(q_{i j}\right)$. Up to re-numbering ( $=$ re-coordinatization), we may assume that the elements $q_{12}, q_{34}, \ldots, q_{2 s-1,2 s} \neq 1$, but $q_{2 i+1,2 i+2}=1$ for all $i \geq s$. Then $Q$ admits a decomposition

$$
Q_{(\mathcal{Z})}=Q_{1, \mathcal{Z}} \otimes_{\mathcal{Z}} \cdots \otimes_{\mathcal{Z}} Q_{s, \mathcal{Z}}
$$

where the $Q_{i, \mathcal{Z}}=\left(t_{2 i-1}, t_{2 i}\right)$ are the symbol algebras in degree $\ell_{i}$ corresponding to the nontrivial diagonal blocks of $q$ of size $2 \times 2$, i.e., to the block diagonal sub-matrices

$$
\left(\begin{array}{cc}
1 & q_{2 i-1,2 i} \\
q_{2 i, 2 i-1} & 1
\end{array}\right)
$$

of $q$ where $i \leq s$. Here $t_{2 i-1}=x_{2 i-1}^{\ell_{i}}, t_{2 i}=x_{2 i}^{\ell_{i}}$ and $\ell_{i}=\left|q_{2 i-1,2 i}\right|$ is the order of $q_{2 i-1,2 i}$. Obviously,

$$
\mathcal{Z}=F\left[t_{1}^{ \pm 1}, \ldots, t_{2 s}^{ \pm 1}, t_{2 s+1}^{ \pm 1}, \ldots, t_{n}^{ \pm 1}\right]
$$

where $t_{2 s+1}=x_{2 s+1}, \ldots, t_{n}=x_{n}$.
1.9. Remark. In the Setting of 1.8 assume that all $l_{i} \in F^{\times}$. Then

$$
E=\mathcal{Z}\left[x_{1}^{ \pm 1}, x_{3}^{ \pm 1}, \ldots, x_{2 s-1}^{ \pm 1}\right] \subset Q_{(\mathcal{Z})}
$$

is a maximal étale $\mathcal{Z}$-subalgebra of $Q_{(\mathcal{Z})}$, and the pair $\left(Q_{(\mathcal{Z})}, E\right)$ gives rise to a reductive $\mathcal{Z}$-group scheme $\mathbf{G L}_{Q_{(\mathcal{Z}}}$, and its maximal torus $\mathbf{S}=R_{E / \mathcal{Z}}\left(\mathbf{G}_{m, E}\right)$.

## 2. Results on $\mathfrak{s l}_{\ell}(Q)$ (mostly in good characteristic)

### 2.1. Associative and Lie algebras

For an arbitrary associative algebra $\mathcal{A}$ over a base ring $R$ we denote by $\mathcal{A}^{\text {op }}$ the opposite algebra: $\mathcal{A}^{\text {op }}=\mathcal{A}$ as $R$-modules but the multiplication is given by $a \cdot \mathcal{A}^{\text {op }} b=b \cdot \mathcal{A} a$. Note that for $\mathrm{M}_{\ell}(\mathcal{A}), \ell \in \mathbb{N}_{+}$, namely the associative $R$-algebra of $\ell \times \ell$-matrices over $\mathcal{A}$, we have

$$
\begin{equation*}
\mathrm{M}_{\ell}(\mathcal{A})^{\mathrm{op}} \simeq \mathrm{M}_{\ell}\left(\mathcal{A}^{\mathrm{op}}\right) \tag{2.1.1}
\end{equation*}
$$

The algebra $\mathcal{A}$ becomes a Lie $R$-algebra, denoted $\operatorname{Lie}(\mathcal{A})$, with respect to the commutator $[a, b]=a b-b a$ as multiplication. We leave it to the reader to check that the map

$$
\begin{equation*}
\iota^{\mathrm{op}}: \operatorname{Lie}\left(\mathcal{A}^{\mathrm{op}}\right) \xrightarrow{\sim} \operatorname{Lie}(\mathcal{A}), \quad a \mapsto-a, \tag{2.1.2}
\end{equation*}
$$

is an isomorphism of Lie $R$-algebras.
Abiding by the traditional notation we put

$$
\operatorname{Lie}\left(\mathrm{M}_{\ell}(\mathcal{A})\right)=\mathfrak{g l}_{\ell}(\mathcal{A})
$$

Thus, combining (2.1.1) and (2.1.2) we obtain a Lie algebra isomorphism, also denoted $\iota^{\mathrm{op}}$,

$$
\iota^{\mathrm{op}}: \mathfrak{g l}_{\ell}\left(\mathcal{A}^{\mathrm{op}}\right) \xrightarrow{\sim} \mathfrak{g l}_{\ell}(\mathcal{A}), \quad x \mapsto-x .
$$

### 2.2. The Lie algebra $\mathfrak{s l}_{\ell}(\mathcal{A})$

Let $\mathcal{A}$ be a unital associative $R$-algebra, and let $\ell \in \mathbb{N}, \ell \geq 2$. The derived algebra of the Lie algebra $\mathfrak{g l}_{\ell}(\mathcal{A})$ of 2.1, is called the special linear Lie algebra $\mathfrak{s l}_{\ell}(\mathcal{A})$ :

$$
\mathfrak{s l}_{\ell}(\mathcal{A})=\left[\mathfrak{g l}_{\ell}(\mathcal{A}), \mathfrak{g l}_{\ell}(\mathcal{A})\right] .
$$

Whenever we consider $\mathfrak{s l}_{\ell}(\mathcal{A})$ in the future, it will implicitly be assumed that $\ell \geq 2$. Obviously, the restriction of the isomorphism $\iota^{\mathrm{op}}$,

$$
\begin{equation*}
\iota^{\mathrm{op}}: \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\mathrm{op}}\right) \xrightarrow{\sim} \mathfrak{s l}_{\ell}(\mathcal{A}), \quad x \mapsto-x \tag{2.2.1}
\end{equation*}
$$

is an isomorphism of Lie $R$-algebras. We will later need the fine structure of $\mathfrak{s l}_{\ell}(\mathcal{A})$. First, we have

$$
\mathfrak{s l}_{\ell}(\mathcal{A})=\left\{x \in \mathfrak{g l}_{\ell}(\mathcal{A}): \operatorname{tr}(x) \in[\mathcal{A}, \mathcal{A}]\right\}
$$

where the trace $\operatorname{tr}(x)$ of $x \in \mathfrak{g l}_{\ell}(\mathcal{A})$ is defined as usual. We denote by $E_{i j}, 1 \leq$ $i, j \leq \ell$ the usual matrix units. It is easy to see that

$$
\begin{align*}
\mathfrak{s l}_{\ell}(A) & =\mathcal{L}_{0} \oplus\left(\bigoplus_{1 \leq i \neq j \leq \ell} \mathcal{A} E_{i j}\right)  \tag{2.2.2}\\
\mathcal{L}_{0} & =[\mathcal{A}, \mathcal{A}] E_{11} \oplus\left\{\sum_{i=1}^{\ell} a_{i} E_{i i}: a_{i} \in \mathcal{A}, \sum_{i} a_{i}=0\right\} .
\end{align*}
$$

In particular, for any unital subalgebra $S$ of $R$ the Lie $S$-algebra $\mathfrak{s l}_{\ell}(\mathcal{A})_{(S)}$ contains

$$
\mathfrak{s l}_{\ell}(S)=\left\{x \in \mathfrak{g l}_{\ell}(S): \operatorname{tr}(x)=0\right\}
$$

as subalgebra. We denote

$$
\begin{equation*}
\mathfrak{h}_{S}=\mathfrak{s l}_{\ell}(S) \cap \mathcal{L}_{0}=\left\{\sum_{i=1}^{\ell} s_{i} E_{i i}: s_{i} \in S, \sum_{i} s_{i}=0\right\} \tag{2.2.3}
\end{equation*}
$$

the diagonal subalgebra of $\mathfrak{s l}_{\ell}(S)$.
We will say that a domain $R$ has good characteristic for $\mathfrak{s l}_{\ell}(\mathcal{A})$ if the characteristic of the fraction field of $R$ is either 0 or $p>3$ and such that $p$ does not divide $\ell$. In that case, if $F$ is a subfield of $R$, the subspace $\mathfrak{h}_{F}$ is an ad-diagonalizable subalgebra of $\mathfrak{s l}_{\ell}(\mathcal{A})_{(F)}$ in the sense of Subsection 2.7, and (2.2.2) is the joint eigenspace decomposition of $\mathfrak{h}_{F}$.

It will be useful later to have a coordinate-free approach to $\mathfrak{s l}_{\ell}(\mathcal{A})$. Namely, we let

$$
\begin{equation*}
V=V_{\mathcal{A}}=\mathcal{A} \oplus \cdots \oplus \mathcal{A}=: \mathcal{A}^{\oplus \ell} \tag{2.2.4}
\end{equation*}
$$

be the free right $\mathcal{A}$-module of rank $\ell$. We denote by $\mathrm{B}=\left\{e_{1}, \ldots, e_{\ell}\right\}$ the standard basis of the $\mathcal{A}$-module $V$ :

$$
\begin{equation*}
e_{1}=(1,0, \ldots, 0), \quad \cdots \quad, e_{\ell}=(0,0, \ldots, 1) \tag{2.2.5}
\end{equation*}
$$

so that

$$
\begin{equation*}
V=\bigoplus_{i=1}^{\ell} e_{i} \mathcal{A} \tag{2.2.6}
\end{equation*}
$$

We let the associative algebra $\operatorname{End}_{\mathcal{A}}(V)$ of $\mathcal{A}$-linear endomorphisms of $V$ act on $V$ from the left. Representing $f \in \operatorname{End}_{\mathcal{A}}(V)$ by the matrix $\operatorname{Mat}_{\mathrm{B}}(f)$ with respect to B provides us with an $R$-algebra isomorphism

$$
\begin{equation*}
\operatorname{Mat}_{\mathrm{B}}: \operatorname{End}_{\mathcal{A}}(V) \xrightarrow{\sim} \mathrm{M}_{\ell}(\mathcal{A}) \tag{2.2.7}
\end{equation*}
$$

and thus also an isomorphism of the associated Lie algebras, $\mathfrak{g l}_{\mathcal{A}}(V) \simeq \mathfrak{g l}_{\ell}(\mathcal{A})$, and of their derived algebras,

$$
\mathfrak{s l}_{\mathcal{A}}(V):=\left[\mathfrak{g l}_{\mathcal{A}}(V), \mathfrak{g l}_{\mathcal{A}}(V)\right] \xrightarrow{\sim} \mathfrak{s l}_{\ell}(\mathcal{A}) .
$$

Moreover, observe

$$
e_{i} \mathcal{A}=E_{i i}(V) \quad \text { and } \quad E_{i j}: e_{j} \mathcal{A} \xrightarrow{\sim} e_{i} \mathcal{A} \text { is an isomorphism of } \mathcal{A} \text {-modules. }
$$

2.3. Lemma. In the Setting of 2.2 assume $\ell \cdot 1_{R} \in R^{\times}$and $\mathcal{A}=\mathcal{Z}(\mathcal{A}) \oplus[\mathcal{A}, \mathcal{A}]$. Then

$$
\mathfrak{g l}_{\ell}(\mathcal{A})=\mathcal{Z}\left(\mathfrak{g l}_{\ell}(\mathcal{A})\right) \oplus \mathfrak{s l}_{\ell}(\mathcal{A}) \quad \text { with } \quad \mathcal{Z}\left(\mathfrak{g l}_{\ell}(\mathcal{A})\right)=\mathcal{Z}(\mathcal{A}) E_{\ell}
$$

where $E_{\ell} \in \mathfrak{g l}_{\ell}(\mathcal{A})$ is the $\ell \times \ell$ identity matrix.
Proof. Straightforward.
The following result, determining the centroid of $\mathfrak{s l}_{\ell}(\mathcal{A})$, is folklore.
2.4. Lemma. Let $R$ be a commutative ring with $\frac{1}{2} \in R$, let $\mathcal{A}$ be a unital associative $R$-algebra, and let $\mathcal{L}=\mathfrak{s l}_{\ell}(\mathcal{A})$ with $\ell \geq 2$. Then for every $z \in \mathcal{Z}(\mathcal{A})$ the map $\zeta_{z}: \mathcal{L} \rightarrow \mathcal{L}, \zeta_{z}\left(\left(x_{i j}\right)\right)=\left(z x_{i j}\right)$, is a centroidal transformation of $\mathcal{L}$. The map

$$
\begin{equation*}
\zeta: \mathcal{Z}(\mathcal{A}) \xrightarrow{\sim} \operatorname{Ctd}(\mathcal{L}), \quad z \mapsto \zeta_{z} \tag{2.4.1}
\end{equation*}
$$

is an isomorphism of associative algebras. In particular,

$$
\begin{equation*}
\mathfrak{s l}_{\ell}(\mathcal{A}) \text { is fgc } \Longleftrightarrow \mathcal{A} \text { is fgc. } \tag{2.4.2}
\end{equation*}
$$

Proof. Since $z[a, b]=[z a, b]$ it is clear that $\zeta_{z}$ is an endomorphism of $\mathcal{L}$. It is also immediate that $\zeta_{z} \in \operatorname{Ctd}(\mathcal{L})$ and that $\zeta$ is an injective homomorphism of associative algebras. Thus it remains to prove surjectivity. Let $\chi \in \operatorname{Ctd}(\mathcal{L})$.

We first consider the case $\ell=2$. For $a, b \in \mathcal{A}$ we define

$$
\begin{aligned}
e(a) & =\left(\begin{array}{ll}
0 & a \\
0 & 0
\end{array}\right), & f(b) & =\left(\begin{array}{ll}
0 & 0 \\
b & 0
\end{array}\right), \\
H(a, b) & =[e(a), f(b)]=\left(\begin{array}{cc}
a b & 0 \\
0 & -b a
\end{array}\right), & h & =H(1,1)=\left(\begin{array}{cc}
1 & 0 \\
0 & -1
\end{array}\right) .
\end{aligned}
$$

Then

$$
\begin{aligned}
\{l \in \mathcal{L}:[h, l]=2 l\} & =e(\mathcal{A}), \quad\{l \in \mathcal{L}:[h, l]=-2 l\}=f(\mathcal{A}), \\
\{l \in \mathcal{L}:[h, l]=0\} & =\operatorname{span}\{H(a, b): a, b \in \mathcal{A}\}=: \mathcal{L}_{0}
\end{aligned}
$$

It follows that $\chi$ leaves $e(\mathcal{A}), f(\mathcal{A})$ and $\mathcal{L}_{0}$ invariant. In particular, we can define $\chi_{ \pm} \in \operatorname{End}(\mathcal{A})$ by

$$
\chi(e(a))=e\left(\chi_{+}(a)\right), \quad \chi(f(b))=f\left(\chi_{-}(b)\right)
$$

Denoting by $\{a b c\}=a b c+c b a$ the Jordan triple product of $\mathcal{A}$, we have the following multiplication rules of $\mathcal{L}$ :

$$
[H(a, b), e(c)]=e(\{a b c\}), \quad[H(a, b), f(c)]=f(-\{b a c\})
$$

They imply $\chi_{ \pm}\left(\left\{\begin{array}{ll}a & b\end{array}\right\}\right)= \begin{cases}a b & \left.\chi_{ \pm}(c)\right\} \text {. Define } z_{ \pm} \in \mathcal{A} \text { by } \chi_{ \pm}\left(1_{\mathcal{A}}\right)=z_{ \pm} \text {. Then, }, \text {. }{ }^{\text {. }} \text {. }\end{cases}$ specializing $a=c=1_{\mathcal{A}}$ we obtain

$$
2 \chi_{ \pm}(b)=\chi_{ \pm}\left(\left\{1_{\mathcal{A}} 1_{\mathcal{A}} b\right\}\right)=b \chi_{ \pm}\left(1_{\mathcal{A}}\right)+\chi_{ \pm}\left(1_{\mathcal{A}}\right) b=2 z_{ \pm} \circ b
$$

where $x \circ y=\frac{1}{2}(x y+y x)$ is the Jordan algebra product of $\mathcal{A}$. Thus $\chi_{ \pm}(b)=z_{ \pm} \circ b$. From $H(a, b)=[e(a), f(b)]$ we now get

$$
H\left(z_{ \pm} \circ a, b\right)=[\chi(e(a)), f(b)]=[e(a), \chi(f(b))]=H\left(a, z_{-} \circ b\right) .
$$

Comparing the (11)-entry of $H$, this proves

$$
z_{+} a b+a z_{+} b=a z_{-} b+a b z_{-} .
$$

In particular, for $a=1_{\mathcal{A}}$ we obtain $2 z_{+} b=z_{-} b+b z_{-}$. Specializing $b=1_{\mathcal{A}}$ in the formula above, this shows $z_{+}=z_{-}=: z$, whence $2 z b=z b+b z$, or $z b=b z$ for all $b \in \mathcal{A}$, i.e., $z \in \mathcal{Z}(\mathcal{A})$. Finally, $\chi(H(a, b))=H(z a, b)=z H(a, b)$ proves $\chi=\zeta_{z}$.

Let now $\ell \geq 3$, and $i \neq j$. From

$$
\mathcal{A} E_{i j}=\left\{l \in \mathfrak{s l}_{\ell}(\mathcal{A}) ;\left[E_{i i}-E_{j j}, l\right]=2 l\right\}
$$

we get $\chi\left(\mathcal{A} E_{i j}\right)=\mathcal{A} E_{i j}$, allowing us to define $\chi_{i j} \in \operatorname{End} \mathcal{A}$ by $\chi\left(a E_{i j}\right)=\chi_{i j}(a) E_{i j}$. For distinct $i, j, p$ and $a, b \in \mathcal{A}$ we have the multiplication formula

$$
a b E_{i j}=\left[\left[\left[a E_{i j}, E_{j p}\right], E_{p i}\right], b E_{i j}\right]
$$

which implies $\chi_{i j}(a b)=\chi_{i j}(a) b=a \chi_{i j}(b)$, i.e., $\chi_{i j} \in \operatorname{Ctd}(\mathcal{A}) \simeq \mathcal{Z}(\mathcal{A})$ by (1.1.3). Thus, there exists $z_{i j} \in \mathcal{Z}(\mathcal{A})$ such that $\chi_{i j}(a)=z_{i j} a$. From $\left[a E_{i j}, E_{j p}\right]=a E_{i p}$ we now obtain $z_{i j}=z_{i p}$ and from $\left[E_{p i}, a E_{i j}\right]=a E_{p i}$ we get $z_{i j}=z_{p j}$. Hence the $z_{i j}$ are independent of $(i j)$, say $z_{i j}=: z \in \mathcal{Z}(\mathcal{A})$. Finally $\chi=\zeta_{z}$ follows.
2.5. Lemma. Let $\ell, \ell^{\prime} \in \mathbb{N}$ with $\ell, \ell^{\prime} \geq 2$, and let $R$ be a commutative base ring for which $2 \cdot 1_{R}, \ell \cdot 1_{R}$ and $\ell^{\prime} \cdot 1_{R}$ are invertible in $R$. Furthermore, let $\mathcal{A}$ and $\mathcal{A}^{\prime}$ be unital associative $R$-algebras satisfying

$$
\mathcal{A}=\mathcal{Z}(\mathcal{A}) \oplus[\mathcal{A}, \mathcal{A}] \quad \text { and } \quad \mathcal{A}^{\prime}=\mathcal{Z}\left(\mathcal{A}^{\prime}\right) \oplus\left[\mathcal{A}^{\prime}, \mathcal{A}^{\prime}\right] .
$$

(a) Let $f: \mathfrak{s l}_{\ell}(\mathcal{A}) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ be an $R$-linear isomorphism of Lie algebras. The $R$-linear algebra isomorphisms $\operatorname{Ctd}(f), \zeta_{\mathcal{A}}$ and $\zeta_{\mathcal{A}^{\prime}}$ of (1.1.1) and (2.4.1) allow us to define an isomorphism $f_{\mathcal{Z}}: \mathcal{Z}(\mathcal{A}) \rightarrow \mathcal{Z}\left(\mathcal{A}^{\prime}\right)$ by requiring commutativity of the diagram

For $z \in \mathcal{Z}(\mathcal{A})$ and $X \in \mathfrak{s l}_{\ell}(\mathcal{A})$ define

$$
f_{\mathfrak{g} 1}: \mathfrak{g l}_{\ell}(\mathcal{A}) \rightarrow \mathfrak{g l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right), \quad z E_{\ell}+X \mapsto f_{\mathcal{Z}}(z) E_{\ell^{\prime}}+f(X) .
$$

Then $f_{\mathfrak{g} r}$ is an isomorphism of Lie algebras. If $\mathfrak{s l}_{\ell}(\mathcal{A})$ and $\mathfrak{g l}_{\ell}(\mathcal{A})$ are viewed as $\mathcal{Z}\left(\mathcal{A}^{\prime}\right)$-algebras via the construction of (1.1.1), then both $f$ and $f_{\mathfrak{g} r}$ are $\mathcal{Z}\left(\mathcal{A}^{\prime}\right)$ linear.
(b) Let $\varphi: \mathrm{M}_{\ell}(\mathcal{A}) \rightarrow \mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ be an isomorphism of associative algebras. The induced Lie algebra isomorphism $\varphi_{\mathfrak{s l}}: \mathfrak{s l}_{\ell}(\mathcal{A}) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ obtained from $\varphi$ satisfies $\left(\varphi_{\mathfrak{s r}}\right)_{\mathfrak{g r}}=\varphi$.

Proof. (a) is immediate from Lemma 2.3 and Lemma 2.4. For (b) we use that $\varphi$ maps the centre $\mathcal{Z}(\mathcal{A}) E_{\ell}$ of $\mathrm{M}_{\ell}(\mathcal{A})$ into the centre $\mathcal{Z}\left(\mathcal{A}^{\prime}\right) E_{\ell^{\prime}}$ of $\mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$, hence induces an $R$-linear isomorphism $\psi: \mathcal{Z}(\mathcal{A}) \rightarrow \mathcal{Z}\left(\mathcal{A}^{\prime}\right)$ by $\varphi\left(z E_{\ell}\right)=\psi(z) E_{\ell^{\prime}}$. Our claim is $\left(\varphi_{\mathfrak{s l}}\right)_{\mathcal{Z}}=\psi$.

Denoting by $L$ and $L^{\prime}$ the left multiplication of the associative algebras $\mathrm{M}_{\ell}(\mathcal{A})$ and $\mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ respectively, we have

$$
\varphi \circ L_{z E_{\ell}} \circ \varphi^{-1}=L_{\varphi\left(z E_{\ell}\right)}^{\prime}=L_{\psi(z) E_{\ell^{\prime}}}^{\prime}
$$

for all $z \in \mathcal{Z}(\mathcal{A})$. Note that $L_{z E_{\ell}}$ stabilizes $\mathfrak{s l}_{\ell}(\mathcal{A})$. We denote by $\left(L_{z E_{\ell}}\right)_{\mathfrak{s l}}$ the restriction of $L_{z E_{\ell}}$ to $\mathfrak{s l}_{\ell}(\mathcal{A})$. Then $\zeta_{\mathcal{A}}(z)=\left(L_{z E_{\ell}}\right)_{\mathfrak{s} l}$. Using analogous notation for $\mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ and taking the $\mathfrak{s l}$-components of the displayed equation above, we get

$$
\begin{aligned}
\left(\operatorname{Ctd}\left(\varphi_{\mathfrak{s l}}\right)^{-1} \circ \zeta_{\mathcal{A}}\right)(z) & =\varphi_{\mathfrak{s l}} \circ \zeta_{\mathcal{A}}(z) \circ \varphi_{\mathfrak{s l}}^{-1}=\varphi_{\mathfrak{s l}} \circ\left(L_{z E_{\ell}}\right)_{\mathfrak{s l}} \circ \varphi_{\mathfrak{s l}}^{-1} \\
& =\left(L_{\psi(z) E_{\ell^{\prime}}}^{\prime}\right)_{\mathfrak{s l}}=\zeta_{\mathcal{A}^{\prime}}(\psi(z))
\end{aligned}
$$

which proves our claim.
2.6. Remark. We will later apply this Lemma in a situation where we are given a Lie algebra isomorphism $f: \mathfrak{s l}_{\ell}(\mathcal{A}) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ and
(a) either $f$ extends to an isomorphism $\widehat{f}: \mathrm{M}_{\ell}(\mathcal{A}) \rightarrow \mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ of associative algebras,
(b) or $f \circ \iota^{\mathrm{op}}: \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\mathrm{op}}\right) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ extends to an $R$-linear isomorphism

$$
\widehat{f \circ \iota^{\mathrm{op}}}: \mathrm{M}_{\ell}\left(\mathcal{A}^{\mathrm{op}}\right) \rightarrow \mathrm{M}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)
$$

of associative algebras.
In the first case, the Lie algebra isomorphism $f_{\mathfrak{g l}}: \mathfrak{g l}_{\ell}(\mathcal{A}) \rightarrow \mathfrak{g l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ of Lemma 2.5 is in fact an isomorphism of associative algebras, namely $\widehat{f}=f_{\mathfrak{g l}}$ (as maps), while in the second case we have $\widehat{f \circ \iota^{\mathrm{op}}}=\left(f \circ \iota^{\mathrm{op}}\right)_{\mathfrak{g} 1}$.
2.7. Definition (AD and MAD subalgebras). We now come to the central concept of this paper. Let $F$ be a field. Following [CGP, $\S 6]$ we call an $F$-subalgebra $\mathfrak{h}$ of a Lie algebra $\mathcal{L}$ over $F$ an $A D$ subalgebra if the adjoint action of each element $x \in \mathfrak{h}$ on $\mathcal{L}$ is $F$-diagonalizable, i.e., $\mathcal{L}$ admits an $F$-basis consisting of eigenvectors of $\operatorname{ad}_{L}(x)$ for all $x \in \mathfrak{h}$.

A maximal AD subalgebra of $\mathcal{L}$, i.e., one which is not properly included in any other AD subalgebra of $\mathcal{L}$, is called a $M A D$ subalgebra, or a $M A D$ for short.

It is not difficult to show, see, for example, [Hu, Lem. 8.1], that an AD subalgebra is necessarily abelian. Hence, AD can be thought of as an abbreviation for "abelian $k$-diagonalizable" or "ad $k$-diagonalizable".

Let $Q$ be a quantum torus over $F$. Denote by $\mathcal{Z}\left(\mathfrak{g l}_{\ell}(Q)\right)$ the centre of the Lie algebra $\mathfrak{g l}_{\ell}(Q)$. Assuming that $F$ is of good characteristic for $\mathfrak{g l}_{\ell}(Q)$, by Lemma 2.3 we have

$$
\mathfrak{g l}_{\ell}(Q)=\mathcal{Z}\left(\mathfrak{g l}_{\ell}(Q)\right) \oplus \mathfrak{s l}_{\ell}(Q), \quad \mathcal{Z}\left(\mathfrak{g l}_{\ell}(Q)\right)=\mathcal{Z}(Q) E_{\ell}
$$

It follows that $\mathfrak{h} \subset \mathfrak{s l}_{\ell}(Q)$ is an AD or a $\operatorname{MAD}$ of $\mathfrak{s l}_{\ell}(Q)$ if and only if $\mathcal{Z}(Q) E_{\ell} \oplus \mathfrak{h}$ is an AD or a MAD of $\mathfrak{g l}_{\ell}(Q)$ respectively.

We next give a first example of a MAD.
2.8. Proposition. Let $Q$ be a quantum torus over a field $F$ of good characteristic for $\mathfrak{s l}_{\ell}(Q), \ell \geq 2$. The subalgebra $\mathfrak{h}_{F}$ of (2.2.3) is a MAD of the Lie algebra $\mathfrak{s l}_{\ell}(Q)_{(F)}$.

We note that in the case that $\mathfrak{s l}_{\ell}(Q)$ is an fgc Lie torus over a field of characteristic 0 , cf. $1.2(\mathrm{f})$ and (2.4.2), the lemma has been proven in [Al, Cor. 5.5]. The methods of [Al] cannot be applied in our case.

Proof. It is clear that $\mathfrak{h}=\mathfrak{h}_{F}$ is an AD: the joint eigenspaces of $\mathfrak{h}$ are the subspaces $Q E_{i j}$ and $\mathcal{L}_{0}$ of (2.2.2). To show maximality, let $d \in \mathfrak{s l}_{\ell}(Q)$ be an ad $F$-diagonalizable element commuting with $\mathfrak{h}$. It follows that $d \in \mathfrak{s l}_{\ell}(Q)_{0}=\{l \in$ $\mathfrak{s l}_{\ell}(Q):[h, l]=0$ for all $\left.h \in \mathfrak{h}\right\}$. Thus, $d=\operatorname{diag}\left(d_{1}, \ldots, d_{\ell}\right)$ is a diagonal matrix. For fixed $i, 1 \leq i \leq \ell$, and $q \in[Q, Q]$ we have $q E_{i i} \in \mathfrak{s l}_{\ell}(Q)_{0}$ and $\left[d, q E_{i i}\right]=\left[d_{i}, q\right] E_{i i}$. Because $Q=\mathcal{Z}(Q) \oplus[Q, Q]$ it follows that ad $d_{i} \in \operatorname{End}_{F}(Q)$ is $F$-diagonalizable. Hence, by Lemma 1.4(b), all $d_{i} \in \mathcal{Z}(Q)$. Consider now the action of $d$ on an off-diagonal space $Q E_{i j}, i \neq j$. Clearly, ad $d$ leaves $Q E_{i j}$ invariant and acts on $q E_{i j}$ by $\left(d_{i}-d_{j}\right) q E_{i j}$, Thus, the left multiplication by $d_{i}-d_{j}$ is diagonalizable, forcing $d_{i}-d_{j} \in F$ by Lemma 1.4(a). Now consider the equation
$[Q, Q] \ni \sum_{i} d_{i}=\left(d_{1}-d_{2}\right)+2\left(d_{2}-d_{3}\right)+\cdots+(n-1)\left(d_{\ell-1}-d_{\ell}\right)+\ell d_{\ell} \in \mathcal{Z}(Q)$.
It follows that $\sum_{i} d_{i}=0$ and that $d_{\ell} \in F$. Analogously, all $d_{i} \in F$, and $d \in \mathfrak{h}$ follows.

### 2.9. Complete orthogonal systems

Let $\mathcal{B}$ be a unital associative $R$-algebra. A complete orthogonal system (of idempotents) in $\mathcal{B}$ is a family $\mathcal{O}=\left(e_{1}, \ldots, e_{m}\right)$ of elements $e_{i} \in \mathcal{B}$ satisfying

$$
\begin{equation*}
e_{i} e_{j}=\delta_{i j} e_{i} \quad \text { for } 1 \leq i, j \leq m \text { and } \quad e_{1}+\cdots+e_{m}=1_{\mathcal{B}} \tag{2.9.1}
\end{equation*}
$$

In $\mathcal{B}=\mathrm{M}_{\ell}(\mathcal{A}), \mathcal{A}$ unital associative, the standard orthogonal system is $\mathcal{O}_{\mathrm{st}}=$ $\left(E_{11}, E_{22}, \ldots, E_{\ell \ell}\right)$, where the $E_{i j}$ are the usual standard matrix units. But also $\left(E_{11}+E_{22}, E_{33}, \ldots, E_{\ell \ell}\right)$ is a complete orthogonal system. Part (a) of the following Lemma 2.10 says that there is a natural bijection between complete orthogonal systems in $\mathrm{M}_{\ell}(\mathcal{A})$ and decompositions of $V_{\mathcal{A}}$ as a direct sum of $\mathcal{A}$-modules.
2.10. Lemma. Let $\mathcal{A}$ be a unital associative $R$-algebra, and let $V=V_{\mathcal{A}}=\mathcal{A}^{\oplus \ell}$ be the right $\mathcal{A}$-module of (2.2.4). We identify $\mathcal{B}=\mathrm{M}_{\ell}(\mathcal{A}) \equiv \operatorname{End}_{\mathcal{A}}(V)$ using (2.2.7).
(a) Let $\mathcal{O}=\left(e_{1}, \ldots, e_{m}\right)$ be a complete orthogonal system in $\mathcal{B}$. Define $V_{i}=$ $e_{i}(V), 1 \leq i \leq m$. Then $V$ decomposes as $V=V_{1} \oplus \cdots \oplus V_{m}$ where each $V_{i}$ is a right $\mathcal{A}$-module. Conversely, let $V=V_{1} \oplus \cdots \oplus V_{m}$ be a decomposition of $V$ as a direct sum of $\mathcal{A}$-modules. Define $e_{i} \in \mathcal{B}$ as the canonical projection of $V$ onto $V_{i} \subset V$. Then $\left(e_{1}, \ldots, e_{m}\right)$ is a complete orthogonal system in $\mathrm{M}_{\ell}(\mathcal{A})$.

The constructions $\mathcal{O} \rightsquigarrow V=V_{1} \oplus \cdots \oplus V_{m}$ and $V=V_{1} \oplus \cdots \oplus V_{m} \rightsquigarrow \mathcal{O}$ defined above are inverses of each other.
(b) Let $\mathcal{O}=\left(e_{1}, \ldots, e_{m}\right)$ and $\mathcal{O}^{\prime}=\left(e_{1}^{\prime}, \ldots, e_{m^{\prime}}^{\prime}\right)$ be complete orthogonal systems in $\mathrm{M}_{\ell}(\mathcal{A})$, inducing by (a) decompositions $V_{\mathcal{A}}=V_{1} \oplus \cdots \oplus V_{m}=V_{1}^{\prime} \oplus \cdots \oplus V_{m^{\prime}}^{\prime}$. Let

$$
\mathcal{D}(\mathcal{O})=\left\{f \in \operatorname{End}_{\mathcal{A}}\left(V_{\mathcal{A}}\right): f\left(V_{i}\right) \subset V_{i}, 1 \leq i \leq m\right\}=\bigoplus_{i=1}^{m} \operatorname{End}_{\mathcal{A}}\left(V_{i}\right)
$$

and define $\mathcal{D}\left(\mathcal{O}^{\prime}\right)$ analogously. Suppose that all $\operatorname{End}_{\mathcal{A}}\left(V_{i}\right)$ and $\operatorname{End}_{\mathcal{A}}\left(V_{j}^{\prime}\right)$ are connected. Then the following are equivalent for $g \in \mathcal{B}^{\times}$.
(i) $g \mathcal{D}(\mathcal{O}) g^{-1}=\mathcal{D}\left(\mathcal{O}^{\prime}\right)$.
(ii) $m=m^{\prime}$ and there exists a permutation $\sigma \in \mathfrak{S}_{m}$ such that $g e_{i} g^{-1}=e_{\sigma(i)}^{\prime}$, $1 \leq i \leq m$.
(iii) $m=m^{\prime}$ and there exists a permutation $\sigma \in \mathfrak{S}_{m}$ such that $g\left(V_{i}\right)=V_{\sigma(i)}^{\prime}$ for $1 \leq i \leq m$.
(c) Let $\mathcal{A}=Q$ be a quantum torus. Let $\mathcal{O}_{\text {st }}=\left(E_{11}, \ldots, E_{\ell \ell}\right)$ be the standard orthogonal system in $\mathcal{B}=\mathrm{M}_{\ell}(Q)$, and let $\mathcal{O}=\left(e_{1}, \ldots e_{\ell}\right)$ be another complete orthogonal system in $\mathcal{B}$ with associated decomposition $V_{Q}=V_{1} \oplus \cdots \oplus V_{\ell}, V_{i}=e_{i}(V)$ for $1 \leq i \leq \ell$. Define $\mathcal{D}\left(\mathcal{O}_{\text {st }}\right)$ and $\mathcal{D}(\mathcal{O})$ as in (b). Then the following are equivalent.
(i) Each $V_{i}, 1 \leq i \leq \ell$, is a cyclic $Q$-module.
(ii) Each $V_{i}, 1 \leq i \leq \ell$, is a free $Q$-module of rank 1 .
(iii) There exists $g \in \mathcal{B}^{\times}$such that $g \mathcal{D}\left(\mathcal{O}_{\text {st }}\right) g^{-1}=\mathcal{D}(\mathcal{O})$ and each $\operatorname{End}_{Q}\left(V_{i}\right)$ is connected.
Assuming (c.iii) holds, let $g \in \mathcal{B}^{\times}$be as in (c.iii) and let

$$
\mathfrak{h}_{\mathrm{st}}=\left\{\sum_{i=1}^{\ell} s_{i} E_{i i}: s_{i} \in F, \sum_{i} s_{i}=0\right\}
$$

be the standard $M A D$ of $\mathfrak{s l}_{\ell}(Q)$ and define $\mathfrak{h} \subset \mathcal{D}(\mathcal{O})$ analogously. Then the automorphism $\operatorname{Int}(g)$ of $\mathfrak{s l}_{\ell}(Q)$ maps $\mathfrak{h}_{\text {st }}$ onto $\mathfrak{h}$. In particular, $\mathfrak{h}$ is also a MAD of $\mathfrak{s l}_{\ell}(Q)$.
Proof. (a) That $V=\sum_{i=1}^{m} V_{i}$ follows from the second equation in (2.9.1), and that the sum is direct from the first. The converse is equally straightforward.
(b) Assume (b.i). Since $\left(g e_{i} g^{-1}\right)_{1 \leq i \leq m}$ is a complete orthogonal system of $\mathcal{B}$ contained in $\mathcal{D}\left(\mathcal{O}^{\prime}\right)$, it follows from our connectedness assumption that each $e_{i} \in \mathcal{O}$ is a sum of some of the $e_{i}^{\prime} \in \mathcal{O}^{\prime}$, and that distinct idempotents in $\mathcal{O}^{\prime}$ are used for each $e_{i}$. Hence $m \leq m^{\prime}$. By symmetry, $m^{\prime} \leq m$, whence $m=m^{\prime}$. The remaining part of (b.ii) is now clear. The implications (b.ii) $\Longrightarrow$ (b.iii) $\Longrightarrow$ (b.i) are immediate from the definitions.
(c) A cyclic $Q$-module is free since $Q$ is a domain. Thus (c.i) $\Longleftrightarrow$ (c.ii). For the proof of $(\mathrm{c} . \mathrm{ii}) \Longrightarrow$ (c.iii) put $V_{i, \mathrm{st}}=E_{i i}(V)$. We know $V_{i, \mathrm{st}} \simeq Q$ by (2.2.6). Also, by assumption, there exist $Q$-linear isomorphisms $g_{i}: V_{i, \text { st }} \rightarrow V_{i}, 1 \leq i \leq \ell$. Hence $g=g_{1} \oplus \cdots \oplus g_{\ell}$ is an invertible endomorphism of $V$ such that $g\left(V_{i, \text { st }}\right)=V_{i}$, $1 \leq i \leq \ell$. It then follows from (b) that $g \mathcal{D}\left(\mathcal{O}_{\mathrm{st}}\right) g^{-1}=\mathcal{D}(\mathcal{O})$ (note that (b) can be applied since $Q \simeq \operatorname{End}_{Q}\left(V_{i}\right)$ is connected by $1.2(\mathrm{~d})$. The implication (c.iii) $\Longrightarrow$ (c.ii) also follows from (b).

## 3. Isomorphisms between two Lie algebras of type $\mathbf{A}$ over rings

### 3.1. Torsion bijections

We start by reviewing some of the techniques of non-abelian Čech cohomology used later on.

Let $\mathbf{G}$ be a smooth affine group scheme over a (commutative, unital) ring $R$. The pointed set of non-abelian Čech cohomology on the étale site of $X=\operatorname{Spec}(R)$
with coefficients in $\mathbf{G}$, is denoted by $H_{e \mathrm{et}}^{1}(X, \mathbf{G})$. This pointed set measures the isomorphism classes of torsors over $X$ under $G$ (see [Mi, Ch. IV §1] and [DG] for basic definitions and references). Abusing notation a bit we will identify the set of isomorphism classes of G-torsors over $X$ with $H_{e ̂ t}^{1}(R, \mathbf{G})$.

Recall that any morphism $\mathbf{G} \rightarrow \mathbf{H}$ of group schemes induces a natural map $H_{\text {êt }}^{1}(R, \mathbf{G}) \rightarrow H_{\text {êt }}^{1}(R, \mathbf{H})$. If $[E] \in H_{\text {êt }}^{1}(R, \mathbf{G})$ we will denote its image in $H_{\text {êt }}^{1}(R, \mathbf{H})$ by $\left[E_{\mathbf{H}}\right]$.

For a $\mathbf{G}$-torsor $E$ we denote by ${ }^{E} \mathbf{G}$ the twisted form of $\mathbf{G}$ by $E$. This is a smooth affine group scheme over $X$. Recall that according to [Gi, III.2.6.3.1] there exists a natural bijection

$$
\tau_{E}: H_{e \mathrm{et}}^{1}\left(X,{ }^{E} \mathbf{G}\right) \rightarrow H_{\mathrm{e} \mathrm{t}}^{1}(X, \mathbf{G}),
$$

called the torsion bijection, which takes the class of the trivial torsor under ${ }^{E} \mathbf{G}$ to the class of $E$.

Let $[E] \in H_{\text {êt }}^{1}(R, \mathbf{G})$. Any exact sequence

$$
1 \rightarrow \mathbf{G} \xrightarrow{\psi} \mathbf{H} \rightarrow \mathbf{F} \rightarrow 1
$$

of smooth affine group schemes induces a commutative diagram

3.2. Lemma. Using the notation of 3.1, the torsion bijection $\tau_{E}$ induces a bijection between $\operatorname{Ker}\left(\psi_{E}\right)$ and the fiber $\psi^{-1}(\psi(E))=\psi^{-1}\left(E_{H}\right)$.

Proof. This follows from an easy diagram chase.

### 3.3. Azumaya algebras

Let $\mathcal{A}$ be an Azumaya algebra over a (commutative, associative, unital) ring $R$. If $\mathcal{A}$ has rank $\ell^{2}$, it is a twisted form of the matrix algebra $\mathrm{M}_{\ell}(R)$. Since

$$
\boldsymbol{A u t}_{R}\left(\mathrm{M}_{\ell}(R)\right) \simeq \mathbf{P} \mathbf{G} \mathbf{L}_{\ell, R}
$$

(see [Mi, Chap. IV, Prop. 2.3]), the elements of $H_{\text {êt }}^{1}\left(R, \mathbf{P G L} \mathbf{L}_{\ell, R}\right)$ are in one-to-one correspondence with the isomorphism classes of Azumaya algebras over $R$ of degree $\ell$ (the bijection is given by twisting). It follows that $\mathcal{A} \simeq{ }^{\xi} \mathrm{M}_{\ell}(R)$ for some class $[\xi] \in H_{\text {êt }}^{1}\left(R, \mathbf{P G} \mathbf{L}_{\ell, R}\right)$ and that $\operatorname{Aut}_{R}(\mathcal{A}) \simeq \mathbf{P G} \mathbf{L}_{\mathcal{A}}$.

### 3.4. Automorphisms of $\mathfrak{s l}_{\mathcal{A}}$

(a) Let $\mathcal{A}$ be an Azumaya algebra over $R$. Every $\varphi \in \operatorname{Aut}(\mathcal{A})(R)$ leaves the Lie algebra

$$
\mathfrak{s l}_{\mathcal{A}}:=[\mathcal{A}, \mathcal{A}]
$$

invariant, thus induces an automorphism $\varphi_{\mathfrak{s l}}$ of $\mathfrak{s l}_{\mathcal{A}}$. Since the construction $\varphi \mapsto$ $\varphi_{\mathfrak{s l}}$ is functorial, it gives rise to a homomorphism

$$
\begin{equation*}
\mathbf{P G L} \mathbf{L}_{\mathcal{A}} \rightarrow \operatorname{Aut}\left(\mathfrak{s l}_{\mathcal{A}}\right) \tag{3.4.1}
\end{equation*}
$$

which is injective since $\mathfrak{s l}_{\mathcal{A}}$ generates $\mathcal{A}$ as an associative algebra.
(b) Assume $\mathcal{A}$ has an anti-automorphism $\kappa$. Then

$$
\kappa_{\mathfrak{s l}}: \mathfrak{s l}_{\mathcal{A}} \rightarrow \mathfrak{s l}_{\mathcal{A}}, \quad x \mapsto-\kappa(x)
$$

is an automorphism of $\mathfrak{s l}_{\mathcal{A}}$. Again by functoriality of the construction, this gives rise to an element of $\operatorname{Aut}\left(\mathfrak{s l}_{\mathcal{A}}\right)$, also denoted $\kappa_{\mathfrak{s} \text {. }}$. In case $\mathcal{A}=\mathrm{M}_{\ell}(R)$ we use the transpose as anti-automorphism and put

$$
\begin{equation*}
\tau: \mathfrak{s l}_{\ell}(R) \rightarrow \mathfrak{s l}_{\ell}(R), \quad x \mapsto-{ }^{t} x . \tag{3.4.2}
\end{equation*}
$$

As before, this gives rise to an automorphism in $\boldsymbol{\operatorname { A u t }}\left(\mathfrak{s l}_{\ell}(R)\right)$, also denoted $\tau$.
(c) Putting together the maps in (a) and (b) we have constructed homomorphisms of $R$-group schemes

$$
\begin{equation*}
\mathbf{P G L}_{2, R} \rightarrow \boldsymbol{\operatorname { A u t }}\left(\mathfrak{s l}_{2}(R)\right) \tag{3.4.3}
\end{equation*}
$$

and for $m \geq 3$

$$
\begin{equation*}
\mathbf{P G L}_{m, R} \rtimes(\mathbb{Z} / 2 \mathbb{Z})_{R} \rightarrow \operatorname{Aut}\left(\mathfrak{s l}_{m}(R)\right) ; \quad(\varphi, \varepsilon) \mapsto \varphi_{\mathfrak{s l}} \circ \tau^{\varepsilon} \tag{3.4.4}
\end{equation*}
$$

The reader will easily check that both maps are injective homomorphisms (one needs the assumption $m \geq 3$ to get injectivity in the second case).
3.5. Theorem. Assume $R$ is a domain of good characteristic for $\mathfrak{s l}_{m}$ containing a field $F$. Then the maps (3.4.3) and (3.4.4) are isomorphisms of $R$-group schemes.

Proof. Since all groups involved are obtained from $F$ by base change, and since base change preserves isomorphism, we may assume that $R=F$ is a field of good characteristic. In this case it is shown in [St, 4.7] (or see [Ja, Thm. IX.5] for $F$ of characteristic 0 and $[\mathrm{Se}, \mathrm{p} .67]$ for characteristic $>0$ ) that for any field extension $E / F$ the maps (3.4.3) and (3.4.4) evaluated at the $E$-points are isomorphisms of abstract groups. In particular this holds for the algebraic closure of $F$. A standard fact in the theory of group schemes (see [KMRT, Prop. 22.5]) then proves the result.

### 3.6. Consequences

We will derive some consequences of Theorem 3.5. Let again $\mathcal{A}$ be an Azumaya algebra over $R$. Assume that $R$ is a domain. Since then $\mathcal{A}$ has constant rank as an $R$-module, it is a twisted form of $M_{\ell}(R)$ for some $\ell$.

For the remainder of this section we will assume that $R$ contains a field of $\operatorname{good}$ characteristic for $\mathfrak{s l}_{\ell}(R)$. We consider the corresponding Lie $R$-algebra $\mathfrak{s l}_{\mathcal{A}}=$
$[\mathcal{A}, \mathcal{A}]$. By a standard twisting argument, it follows from Theorem 3.5 that we have an $R$-group scheme isomorphism

$$
\mathbf{P G} \mathbf{L}_{\mathcal{A}} \simeq \operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)
$$

if $\ell=2$, and the exact sequence of $R$-group schemes.

$$
1 \rightarrow \mathbf{P G L}_{\mathcal{A}} \rightarrow \mathbf{A u t}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right) \rightarrow(\mathbb{Z} / 2 \mathbb{Z})_{R} \rightarrow 1
$$

if $\ell \geq 3$.
Evaluating at $R$-points we have

$$
1 \rightarrow \mathrm{PGL}_{\mathcal{A}}=\mathbf{P G L}_{\mathcal{A}}(R) \hookrightarrow \operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)=\operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)(R) \rightarrow \mathbb{Z} / 2 \mathbb{Z}
$$

Note that this last map is trivial when $\ell=2$. We will say that an automorphism $\phi \in \operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)$ is inner if it is in the image of $\mathrm{PGL}_{\mathcal{A}}$. Otherwise we say that $\phi$ is outer.
3.7. Theorem. Let $\phi \in \operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)$. Then the following holds:
(a) If $\phi$ is inner, it is the restriction of a unique automorphism $\psi: \mathcal{A} \rightarrow \mathcal{A}$.
(b) If $\phi$ is outer, it is the restriction of the negative of a unique anti-automorphism $\psi: \mathcal{A} \rightarrow \mathcal{A}$.

Proof. The subset $Y=\operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right) \backslash \mathbf{P G L} \mathbf{L}_{\mathcal{A}}$ is a closed subscheme of $\mathbf{A u t}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)$ consisting of outer automorphisms of $\mathfrak{s l}_{\mathcal{A}}$. The group $\mathbf{P G L} \mathcal{A}_{\mathcal{A}}$ acts simply transitively on $Y$ by left multiplication. Thus $Y$ is a $\mathbf{P G L} \mathbf{L}_{\mathcal{A}}$-torsor. It is trivial if and only if $\mathfrak{s l}_{\mathcal{A}}$ has at least one outer automorphism.

Along the same lines, let $X$ be the scheme of anti-automorphisms of $\mathcal{A}$ :

$$
X=\{\psi: \mathcal{A} \rightarrow \mathcal{A} \mid \psi \text { is bijective and } \psi(x y)=\psi(y) \psi(x) \text { for all } x, y \in \mathcal{A}\}
$$

We observe that if $\psi$ is an anti-automorphism of $\mathcal{A}$ and $\ell \geq 3$ then $-\left.\psi\right|_{\mathfrak{s r}_{\mathcal{A}}}$ is an outer automorphism of $\mathfrak{s l}_{\mathcal{A}}$. The automorphism group $\mathbf{P G L} \mathcal{L}_{\mathcal{A}}$ of $\mathcal{A}$ acts simply transitively on $X$ on the left (because the action is simply transitively in the split case). Thus, $X$ is also a $\mathbf{P G L}_{\mathcal{A}}$-torsor. As before, if $\ell \geq 3$ then $X$ is a trivial torsor, i.e., there exists at least one anti-automorphism of $\mathcal{A}$, if and only if $\mathfrak{s l}_{\mathcal{A}}$ has at least one outer automorphism.

Note that the natural restriction map $\lambda: X \rightarrow Y$ which takes $\psi$ into $-\left.\psi\right|_{\mathfrak{s} I_{\mathcal{A}}}$ is an isomorphism of torsors (because it is an isomorphism in the split case).
(a) Let $\phi$ be inner. Then there exists a unique $g \in \mathbf{P G} \mathbf{L}_{\mathcal{A}}(R)$ whose image in $\operatorname{Aut}_{R}\left(\mathfrak{s l}_{\mathcal{A}}\right)$ is $\phi$. This element $g$ corresponds to the automorphism of $\mathcal{A}$ which we denote by $\psi: \mathcal{A} \rightarrow \mathcal{A}$. By construction, the restriction $\left.\psi\right|_{\mathfrak{s} \mathfrak{L}_{\mathcal{A}}}$ is $\phi$. The uniqueness of such a $\psi$ is immediate, since $\mathfrak{s l}_{\mathcal{A}}$ generates $\mathcal{A}$ as associative algebra.
(b) Now let $\phi$ be outer. Then since $\lambda$ is bijective there exists a unique $\psi \in X(R)$ such that $\lambda(\psi)=-\left.\psi\right|_{\mathfrak{s} \mathfrak{I}_{\mathcal{A}}}$ equals $\phi$.
3.8. Corollary. Let $\mathcal{A}$ be an Azumaya algebra over $R$, thus a twisted form of $\mathrm{M}_{\ell}(R)$. Assume $\ell \geq 3$. Then $\mathcal{A} \simeq \mathcal{A}^{\mathrm{op}}$ if and only if $\mathfrak{s l}_{\mathcal{A}}$ has an outer automorphism.

Proof. Assume $\mathcal{A} \simeq \mathcal{A}^{\text {op }}$. We have seen in 3.4(b) that an isomorphism $\kappa: \mathcal{A} \rightarrow \mathcal{A}^{\mathrm{op}}$ induces an automorphism $\kappa_{\mathfrak{s l}}$ of $\mathfrak{s l}_{\mathcal{A}}$. We claim that $\kappa_{\mathfrak{s l}}$ is an outer automorphism. It suffices to show this after some base change. Take any base change $R \rightarrow S$ which splits $\mathcal{A}$, i.e., $\mathcal{A}_{S} \simeq \mathrm{M}_{\ell}(S)$. Then $\kappa$ is a composite of an inner conjugation, say $\operatorname{int}(g)$, and the transpose $\tau$. It is well known that for $\ell \geq 3$ the restriction of $-\tau$ to $\mathfrak{s l}_{\ell}$ is an outer automorphism (because it induces the automorphism -1 of the corresponding root system), while the restriction of $\operatorname{int}(g)$ to $\mathfrak{s l}_{\mathcal{A}}$ is an inner automorphism. Therefore $\kappa_{\mathfrak{s l}}$ is indeed outer.

The other direction follows from Theorem 3.7(b).
3.9. Theorem. Let $\mathcal{A}, \mathcal{A}^{\prime}$ be Azumaya algebras over our domain $R$ of the same rank $l^{2}$. If $\mathfrak{s l}_{\mathcal{A}} \simeq \mathfrak{s l}_{\mathcal{A}^{\prime}}$ as $R$-algebras, then
(a) $\mathcal{A}^{\prime} \simeq \mathcal{A}$ if $\ell=2$;
(b) $\mathcal{A}^{\prime} \simeq \mathcal{A}$ or $\mathcal{A}^{\prime} \simeq \mathcal{A}^{\mathrm{op}}$ if $\ell \geq 3$.

We note that the converses in (a) and (b) are obvious.
Proof. We abbreviate $H^{1}=H_{\text {êt }}^{1}$ and let $[\xi],\left[\xi^{\prime}\right] \in H^{1}\left(R, \mathbf{P G} \mathbf{L}_{\ell, R}\right)$ be the classes corresponding to $\mathcal{A}$ and $\mathcal{A}^{\prime}$. Because $\mathcal{A}={ }^{\xi} \mathrm{M}_{\ell}(R)$ the Lie algebra $\mathfrak{s l}_{\mathcal{A}}$ is the twisted form of $\mathfrak{s l}_{\ell}(R)$ by $\xi$.

Case $\ell=2$ : Recall from Theorem 3.5 that

$$
\mathbf{A u t}_{R}\left(\mathfrak{s l}_{2}(R)\right)=\mathbf{P G L} \mathbf{L}_{2, R},
$$

i.e., the Lie algebra $\mathfrak{s l}_{2}(R)$ and the Azumaya algebra $\mathrm{M}_{2}(R)$ have the same automorphism group scheme. Therefore, if the twisted forms $\mathfrak{s l}_{\mathcal{A}}$ and $\mathfrak{s l}_{\mathcal{A}^{\prime}}$ of the Lie algebra $\mathfrak{s l}_{2}(R)$ are isomorphic, then $[\xi]=\left[\xi^{\prime}\right]$ implies $\mathcal{A} \simeq \mathcal{A}^{\prime}$ as $R$-algebras.

Case $\ell \geq 3$ : Recall from Theorem 3.5 that

$$
\boldsymbol{A u t}_{R}\left(\mathfrak{s l}_{\ell}(R)\right)=\mathbf{A u t}_{R}\left(\mathbf{P G L} \mathbf{L}_{\ell, R}\right)=\mathbf{P G} \mathbf{L}_{\ell, R} \rtimes(\mathbb{Z} / 2 \mathbb{Z})_{R} .
$$

Hence we get the exact sequence of group schemes

$$
\begin{equation*}
1 \rightarrow \mathbf{P G L}_{\ell, R} \rightarrow \operatorname{Aut}_{R}\left(\mathfrak{s l}_{\ell}(R)\right) \rightarrow(\mathbb{Z} / 2 \mathbb{Z})_{R} \rightarrow 1 \tag{3.9.1}
\end{equation*}
$$

which induces a canonical map

$$
H^{1}\left(R, \mathbf{P G} \mathbf{L}_{\ell, R}\right) \xrightarrow{\psi} H^{1}\left(R, \boldsymbol{\operatorname { A u t }}_{R}\left(\mathfrak{s l}_{\ell}(R)\right)=H^{1}\left(R, \boldsymbol{\operatorname { A u t }}_{R}\left(\mathbf{P G} \mathbf{L}_{\ell, R}\right)\right)\right.
$$

in cohomology. By assumption, $\psi([\xi])=\psi\left(\left[\xi^{\prime}\right]\right)$ (because $\mathfrak{s l}_{\mathcal{A}} \stackrel{R}{\sim} \mathfrak{s l}_{\mathcal{A}^{\prime}}$ ). If $[\xi]=\left[\xi^{\prime}\right]$ then the twisted Azumaya algebras $\mathcal{A}={ }^{\xi} \mathrm{M}_{\ell}(R)$ and $\mathcal{A}^{\prime}=\xi^{\prime} \mathrm{M}_{\ell}(R)$ are isomorphic as $R$-algebras, and we are done.

Assume therefore $[\xi] \neq\left[\xi^{\prime}\right]$. Twisting (3.9.1) by $\xi$ we get an exact sequence of group schemes

$$
1 \rightarrow \mathbf{P G L}_{\mathcal{A}} \rightarrow \boldsymbol{A u t}_{R}\left(\mathbf{P G L} \mathcal{A}_{\mathcal{A}}\right) \rightarrow(\mathbb{Z} / 2 \mathbb{Z})_{R} \rightarrow 1
$$

which in turn induces an exact sequence

$$
\begin{align*}
\mathbf{P G L}_{\mathcal{A}}(R) & \hookrightarrow \operatorname{Aut}_{R}\left(\mathbf{P G} \mathbf{L}_{\mathcal{A}}\right)(R) \rightarrow \mathbb{Z} / 2 \mathbb{Z} \\
& \rightarrow H^{1}\left(R, \mathbf{P G} \mathbf{L}_{\mathcal{A}}\right) \xrightarrow{\phi} H^{1}\left(R, \mathbf{A u t}_{R}\left(\mathbf{P G} \mathbf{L}_{\mathcal{A}}\right)\right) \tag{3.9.2}
\end{align*}
$$

of pointed sets. According to Lemma 3.2 there is a natural one-to-one correspondence between the fiber $\psi^{-1}(\psi(\xi))$ and the kernel of $\phi$. Since $[\xi] \neq\left[\xi^{\prime}\right] \in$ $\psi^{-1}(\psi(\xi))$, the class [ $\left.\xi^{\prime}\right]$ corresponds to some nontrivial element in $\operatorname{Ker}(\phi)$. On the other hand, by (3.9.2), $\operatorname{Ker}(\phi)$ consists of at most two elements implying $|\operatorname{Ker}(\phi)|=2$. We then get from (3.9.2) that $\mathbf{P G L} \mathcal{A}_{\mathcal{A}}(R)=\boldsymbol{A u t}_{R}\left(\mathbf{P G L} \mathcal{A}_{\mathcal{A}}\right)(R)$, i.e., every automorphism of $\mathrm{PGL}_{\mathcal{A}}$ over $R$ is inner. By Corollary 3.8, this implies $\mathcal{A} \not 千 \mathcal{A}^{\mathrm{op}}$.

Now we observe that the opposite Azumaya algebra $\mathcal{A}^{\mathrm{op}}$ also corresponds to some element in $H^{1}\left(R, \mathbf{P G L} \mathbf{L}_{\ell, R}\right)$, call it $\left[\xi^{\mathrm{op}}\right]$. We have $[\xi] \neq\left[\xi^{\mathrm{op}}\right]$ because $\mathcal{A} \not \approx$ $\mathcal{A}^{\text {op }}$. Furthermore, it is straightforward to verify that the map $\mathbf{G} \mathbf{L}_{\mathcal{A}} \rightarrow \mathbf{G} \mathbf{L}_{\mathcal{A}^{\text {op }}}$, given by $x \rightarrow x^{-1}$, is an isomorphism of group schemes which induces in turn an isomorphism $\mathbf{P G L} \mathcal{A}_{\mathcal{A}} \rightarrow \mathbf{P G L} \mathcal{A}_{\mathcal{A}^{\text {op }}}$. This implies that $\psi([\xi])=\psi\left(\left[\xi^{\mathrm{op}}\right]\right)$, hence the class $\left[\xi^{\mathrm{op}}\right]$ also corresponds to the nontrivial element $(\neq[\xi])$ in the fiber $\psi^{-1}(\psi([\xi]))$. Since $\left|\psi^{-1}(\psi([\xi]))\right|=|\operatorname{Ker}(\phi)|=2$, necessarily $\left[\xi^{\prime}\right]=\left[\xi^{\mathrm{op}}\right]$ in $H^{1}\left(R, \mathbf{P G L} \mathbf{L}_{\ell, R}\right)$, implying $\mathcal{A}^{\prime} \simeq \mathcal{A}^{\mathrm{op}}$.

As a by-product of the proof we obtain that the converse statement in Corollary 3.8 also holds.
3.10. Corollary. Let $\mathcal{A}$ be an Azumaya algebra over $R$ of rank $\ell^{2} \geq 4$, where $R$ has good characteristic for $\mathfrak{s l}_{\ell}(R)$. Suppose $\mathcal{A} \nsim \mathcal{A}^{\mathrm{op}}$. Then every automorphism of the Lie $R$-algebra $\mathfrak{s l}_{\mathcal{A}}$ is inner. If in addition $\operatorname{Pic}(R)=1$ then every automorphism of $\mathfrak{s l}_{\mathcal{A}}$ is the restriction of the conjugation map by an element $a \in \mathcal{A}^{\times}$.
Proof. Without loss of generality we may assume that $\ell \geq 3$. We use the notation of Theorem 3.9. Since $\mathcal{A} \not \not \mathcal{A}^{\text {op }}$ we have $[\xi] \neq\left[\xi^{\mathrm{op}}\right]$. Therefore, in sequence (3.9.2) the kernel of the canonical map $\phi$ consists of two elements and this implies $\mathbf{P G L} \mathcal{A}_{\mathcal{A}}(R)=\operatorname{Aut}_{R}\left(\mathbf{P G L} \mathcal{A}_{\mathcal{A}}\right)(R)=\operatorname{Aut}(\mathcal{A})$. Thus every automorphism of $\mathfrak{s l}_{\mathcal{A}}$ is induced by an automorphism of $\mathcal{A}$. It remains to note that if $\operatorname{Pic}(R)=1$ the natural map $\mathcal{A}^{\times} \rightarrow \mathbf{P G L} \mathcal{A}_{\mathcal{A}}(R)$ is surjective.

In the following sections we apply all these results to the case of fgc quantum tori viewed over their centres.

## 4. $\mathfrak{s l}_{\ell}(Q)$ for $Q$ an fgc quantum torus

Our analysis will use the following description of isomorphisms between special linear Lie algebras over rings. The theorem below is an immediate consequence of our Theorem 3.7 and is originally due to Jacobson-Seligman when the Lie algebras in question are defined over fields.
4.1. Theorem. Let $\mathcal{A}$ and $\mathcal{A}^{\prime}$ be Azumaya algebras of the same rank over a domain $R$ containing a field of good characteristic. Let $f: \mathfrak{s l}_{\mathcal{A}^{\prime}} \rightarrow \mathfrak{s l}_{\mathcal{A}}$ be an $R$-linear isomorphism of Lie algebras. Then after possibly replacing $\mathcal{A}$ by $\mathcal{A}^{\text {op }}$, the map $f$ uniquely extends to an $R$-linear isomorphism $\tilde{f}: \mathcal{A}^{\prime} \rightarrow \mathcal{A}$ of associative algebras.

Proof. Since it is clear that $f \circ \iota^{\text {op }}$ is a Lie $R$-algebra isomorphism, we only need to show that $f$ extends to a map $\tilde{f}: \mathcal{A}^{\prime} \rightarrow \mathcal{A}$ which is either an isomorphism or the negative of an anti-isomorphism of associative algebras. By Theorem 3.9, after possibly replacing $\mathcal{A}$ by $\mathcal{A}^{\mathrm{op}}$ we can assume that there exists an isomorphism $g: \mathcal{A}^{\prime} \rightarrow \mathcal{A}$ of associative $R$-algebras. Since the composition $\left.f \circ g^{-1}\right|_{\mathfrak{s i}_{\mathcal{A}}}$ is an $R$ automorphism of $\mathfrak{s l}_{\mathcal{A}}$, by Theorem 3.7 it can be extended uniquely to either an automorphism or the negative of an anti-automorphism of $\mathcal{A}$ and the assertion follows.
4.2. Remark. For the special case of central-simple algebras over a field $K$ of characteristic 0 , the theorem is proven in [Ja, Thm. IX.5]. The characteristic 0 case can easily be extended to positive characteristic by using the description of Aut $\mathfrak{s l}_{\ell}(K)$ in [Se, p. 67].

We will apply this result in the case that $\mathcal{A}$ and $\mathcal{A}^{\prime}$ are matrix algebras over fgc quantum tori.
4.3. Theorem. Let $\mathcal{L}=\mathfrak{s l}_{\ell}(Q)$ and $\mathcal{L}^{\prime}=\mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)$ where $Q$ and $Q^{\prime}$ are fgc quantum tori over a field $F$ of good characteristic for $\mathcal{L}$ and $\mathcal{L}^{\prime}$. We denote by $\mathcal{Z}=\mathcal{Z}(Q)$ the centre of $Q$, and let $f: \mathcal{L}^{\prime} \rightarrow \mathcal{L}$ be an $F$-linear isomorphism of Lie algebras. Then the following hold.
(a) After possibly replacing $Q$ by $Q^{\mathrm{op}}$, the map $f$ uniquely extends to a $\mathcal{Z}$-linear isomorphism $\tilde{f}: \mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)_{(\mathcal{Z})} \rightarrow \mathrm{M}_{\ell}(Q)_{(\mathcal{Z})}$ of associative algebras.
(b) $\ell^{\prime}=\ell$.

Proof. (a) By 2.4 the centre $\mathcal{Z}$ of $Q$ is isomorphic to the centroid of $\mathcal{L}$ - we will take this as an identification. Applying 1.1, Example 1, our map $f$ is a $\mathcal{Z}$-linear isomorphism

$$
f: \mathcal{L}_{(Z)}^{\prime}=\mathfrak{s l}_{\ell^{\prime}}\left(Q_{(\mathcal{Z})}^{\prime}\right) \xrightarrow{\sim} \mathcal{L}_{(\mathcal{Z})}=\mathfrak{s l}_{\ell}\left(Q_{(\mathcal{Z})}\right)
$$

Observe that the two Azumaya algebras $\mathrm{M}_{\ell}(Q)$ and $\mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)$ over $\mathcal{Z}$ have the same rank. Indeed, passing to a proper étale base extension we may assume that they are split. Let $m^{2}$ and $\left(m^{\prime}\right)^{2}$ be their ranks. Then $\operatorname{dim} \mathcal{L}=m^{2}-1$ and $\operatorname{dim} \mathcal{L}^{\prime}=\left(m^{\prime}\right)^{2}-1$ implying $m=m^{\prime}$. Now Theorem 4.1 applied to $\mathcal{A}=\mathrm{M}_{\ell}(Q)_{(\mathcal{Z})}$ and $\mathcal{A}^{\prime}=\mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)_{(\mathcal{Z})}$ implies the claim.
(b) Let $K$ be the fraction field of $\mathcal{Z}$ (recall from $1.2(\mathrm{~b})$ that $\mathcal{Z}$ is a Laurent polynomial ring over $F$ ). Then after possibly replacing $Q$ by $Q^{\text {op }}$ we can assume that $\tilde{f}$ uniquely extends to a $K$-linear isomorphism

$$
\tilde{f}_{K}: M_{\ell^{\prime}}\left(Q^{\prime}\right) \otimes_{\mathcal{Z}} K \xrightarrow{\sim} M_{\ell}(Q) \otimes_{\mathcal{Z}} K
$$

of associative algebras. But $D^{\prime}=Q_{(\mathcal{Z})}^{\prime} \otimes_{\mathcal{Z}} K$ and $D=Q_{(\mathcal{Z})} \otimes_{\mathcal{Z}} K$ are central division algebras over $K$. Now by the theorem of Wedderburn (see [He, Thm. 2.1.6]) we have $D^{\prime} \simeq D$ and $\ell^{\prime}=\ell$.

The spirit of Theorem 4.3, in a sense that will be made precise, will allow us to reduce questions of isomorphisms of Lie algebras to questions of isomorphisms of associative algebras. These are handled in the following result.
4.4. Theorem. Let $Q$ and $Q^{\prime}$ be fgc quantum tori over the field $F$ and let $\mathcal{A}=$ $\mathrm{M}_{\ell}(Q)$ and $\mathcal{A}^{\prime}=\mathrm{M}_{\ell}\left(Q^{\prime}\right)$. We assume that the characteristic of $F$ is very good: it is either 0 , or $p>3$ where $p$ does not divide $\ell$ or any of the $q_{i j}, q_{i j}^{\prime}$ occurring in the quantum matrices of $Q$ and $Q^{\prime}$ respectively with respect to a canonical presentation. We let $\mathcal{Z}$ be the centre of $Q$, and assume that $f: \mathcal{A}^{\prime} \rightarrow \mathcal{A}$ is an $F$-linear isomorphism of associative algebras. As in 1.1 we will view $f$ as a $\mathcal{Z}$-linear isomorphism $\mathcal{A}_{(\mathcal{Z})}^{\prime} \rightarrow \mathcal{A}_{(\mathcal{Z})}$. The isomorphism $f$ induces an isomorphism $\phi: G^{\prime} \rightarrow G$ of the associated reductive group schemes $G^{\prime}=\mathbf{G} \mathbf{L}_{A_{(\mathcal{Z})}^{\prime}}$ and $G=\mathbf{G} \mathbf{L}_{A_{(\mathcal{Z}}}$ over $\mathcal{Z}$. Let $T^{\prime}$ (resp. $\left.T\right)$ be the split torus in $G^{\prime}$ (resp. $G$ ) corresponding to the diagonal matrices in $A_{(\mathcal{Z})}^{\prime}=\mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})}^{\prime}\right)$ (resp. in $A_{(\mathcal{Z})}=\mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})}\right)$ ). Then $\phi\left(T^{\prime}\right)$ and $T$ are conjugate in $G$.

Proof. Clearly, $T^{\prime}$ and $T$ are generically maximal split tori in the sense of [CGP], i.e., $T_{K}^{\prime}$ and $T_{K}$ are maximal split tori in $G_{K}$ and $G_{K}^{\prime}$ where $K=\tilde{\mathcal{Z}}$ is the fraction field of $\mathcal{Z}$ (because $\widetilde{Q}=Q_{(\mathcal{Z})} \otimes_{\mathcal{Z}} K$ and $\widetilde{Q^{\prime}}(\mathcal{Z}) \otimes_{\mathcal{Z}} K$ are central division algebras over $K$ by $1.2(\mathrm{~g})$ ). Note that the centralizer of $T$ (resp. $T^{\prime}$ ) in $G$ (resp. in $G^{\prime}$ ) is isomorphic to the reductive group scheme $C_{G}(T) \simeq \mathbf{G} \mathbf{L}_{Q_{(z)}} \times \cdots \times \mathbf{G} \mathbf{L}_{Q_{(z)}}$ over $\mathcal{Z}\left(\right.$ resp. $\left.C_{G^{\prime}}\left(T^{\prime}\right) \simeq \mathbf{G} \mathbf{L}_{Q_{(\mathcal{Z})}^{\prime}} \times \cdots \times \mathbf{G L}_{Q_{(\mathcal{Z})}^{\prime}}\right)$.

Since $T^{\prime}$ and $T$ are generically maximal split tori, the proof of [CGP, Prop. 8.1] shows that an obstacle for conjugacy of $\phi\left(T^{\prime}\right)$ and $T$ in $G$ is given by a class

$$
[\xi] \in H_{\mathrm{Zar}}^{1}\left(\mathcal{Z}, C_{G}(T)\right)=H_{\mathrm{Zar}}^{1}\left(\mathcal{Z}, \mathbf{G L}_{Q_{(\mathcal{Z})}}\right) \times \cdots \times H_{\mathrm{Zar}}^{1}\left(\mathcal{Z}, \mathbf{G} \mathbf{L}_{Q_{(\mathcal{Z})}}\right)
$$

and that

$$
\xi\left(C_{G}(T)\right) \simeq C_{G}\left(\phi\left(T^{\prime}\right)\right) \simeq C_{G^{\prime}}\left(T^{\prime}\right) \simeq \mathbf{G} \mathbf{L}_{\left.Q_{(\mathcal{z}}^{\prime}\right)} \times \cdots \times \mathbf{G}_{Q_{(\mathcal{z})}^{\prime}}
$$

Let $\xi=\left(\xi_{1}, \ldots, \xi_{\ell}\right)$. Since ${ }^{\xi_{i}} \mathbf{G} \mathbf{L}_{Q_{(\mathcal{Z})}} \simeq \mathbf{G} \mathbf{L}_{Q_{(\mathcal{Z})}^{\prime}}$, for the proof of conjugacy of $\phi\left(T^{\prime}\right)$ and $T$ it suffices to show that $\xi_{i}=1$.

We now recall some general facts from the theory of reductive group schemes. Let $H$ be any reductive group scheme over $\mathcal{Z}, S \subset H$ a maximal torus and $[\xi] \in$ $H_{\text {ét }}^{1}(\mathcal{Z}, H)$. Let $N=N_{H}(S)$ and $W=N / S$.
(i) $B y$ [CGP, Lem. 8.2], $W$ is a finite étale $\mathcal{Z}$-group and the canonical map $H_{\text {êt }}^{1}(\mathcal{Z}, W) \rightarrow H_{\text {ét }}^{1}(K, W)$ is injective; in particular $H_{\mathrm{Zar}}^{1}(\mathcal{Z}, W)=1$.
(ii) According to [Gi, Rem. 3.2.5] if the twisted group scheme ${ }^{\xi} H$ contains a maximal torus then the class $[\xi]$ is in the image of $H_{\text {ett }}^{1}\left(\mathcal{Z}, N_{H}(S)\right) \rightarrow$ $H_{\text {ét }}^{1}(\mathcal{Z}, H)$.
(iii) Let $S^{\prime} \subset H$ be another maximal torus. Then the transporter $\boldsymbol{\operatorname { T r a n s }}_{H}\left(S, S^{\prime}\right)$ is an $N$-torsor over $\mathcal{Z}$, hence it corresponds to a unique class $\lambda \in H_{\mathrm{ett}}^{1}(\mathcal{Z}, N)$. If $S, S^{\prime}$ are conjugate over $K$ then $\lambda$ is in the image of $H_{\text {ett }}^{1}(\mathcal{Z}, S) \rightarrow$ $H_{\text {et }}^{1}(\mathcal{Z}, N)$. If in addition $H^{1}(\mathcal{Z}, S)=1$ then $S$ and $S^{\prime}$ are conjugate over $\mathcal{Z}$.

For the proof of the first statement in (iii) we refer to [CGP, Lem. 8.3]. The second assertion follows from (i) and the commutativity of the following diagram:

We will apply these facts in the following two situations. Let $m$ be an integer such that the matrix algebra $\mathrm{M}_{m}(\mathcal{Z})$ is the split form of $Q_{(\mathcal{Z})}$. Take the pair $(E, S)$ consisting of a maximal commutative étale subalgebra $E \subset Q_{(\mathcal{Z})}$ and the corresponding torus $S=R_{E / \mathcal{Z}}\left(\mathbf{G}_{m, E}\right)$ constructed in Remark 1.9. Fix any embedding $E \hookrightarrow \mathrm{M}_{m}(\mathcal{Z})$ (for instance, we can take the regular representation of $E$ ). This also gives rise to a closed embedding $S \hookrightarrow H=\mathbf{G} \mathbf{L}_{m, \mathcal{Z}}$. Note that the torus $S$ determines uniquely the subalgebra $E$. Indeed, $E$ is the centralizer of $S(\mathcal{Z})$ in $\mathrm{M}_{m}(\mathcal{Z})$. When we view $E$ as a subalgebra in $Q_{(\mathcal{Z})}$ we will denote it by $E_{Q}$. Similarly the corresponding torus $S$ will be denoted by $S_{Q}$. Consider now another embedding $E \rightarrow \mathrm{M}_{m}(\mathcal{Z})$. We denote its image by $E^{\prime}$ and the corresponding torus by $S^{\prime}$.
4.5. Lemma. The two étale subalgebras $E, E^{\prime} \subset \mathrm{M}_{m}(\mathcal{Z})$ are conjugate under the action of $\mathbf{G L}_{m}(\mathcal{Z})$.

Proof. It suffices to show the conjugacy of $S$ and $S^{\prime}$. The obstacle for conjugacy of $S, S^{\prime}$ is the $N$-torsor $\operatorname{Trans}_{H}\left(S, S^{\prime}\right)$ where $N=N_{\mathbf{G L}_{m, \mathcal{Z}}}(S)$. By the SkolemNoether Theorem (see [KMRT, Thm. 1.4]) the algebras $E$ and $E^{\prime}$ are conjugate over $K$. Furthermore, we have

$$
H_{\mathrm{et}}^{1}(\mathcal{Z}, S)=H_{\mathrm{et}}^{1}\left(E, \mathbf{G}_{m, E}\right)=\operatorname{Pic}(E)=1
$$

because $E$ is a Laurent polynomial ring and hence has trivial Picard group. The claim now follows from (iii).

We next pass to adjoint groups.
4.6. Lemma. We keep the above notation. Let $\bar{H}=\mathbf{P G L}{ }_{m, \mathcal{Z}}$ and let $\bar{S}$ be the image of $S$ under the canonical map $\mathbf{G L}_{m, \mathcal{Z}} \rightarrow \mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}}$. There exists a class $[\theta] \in H^{1}(\mathcal{Z}, \bar{S})$ such that ${ }^{\theta} \mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}} \simeq \mathbf{P G} \mathbf{L}_{Q_{(z)}}$.
Proof. Since $\mathbf{P G} \mathbf{L}_{Q_{(\mathcal{Z})}}$ has a maximal torus, by (ii) the group scheme $\mathbf{P G L} \mathbf{Q}_{(\mathcal{Z})}$ is a twisted form of $\mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}}$ by some cocycle $\lambda$ with coefficients in $\bar{N}=N_{\mathbf{P G L}_{m, \mathcal{Z}}}(\bar{S})$. The cohomological class [ $\lambda$ ] corresponds to the maximal torus $\bar{S}_{Q} \subset \mathbf{P G L} \mathbf{L}_{Q_{(z)}}$ where $\bar{S}_{Q}$ is the image of $S_{Q} \subset \mathbf{G L}_{Q_{(\mathcal{z})}}$ under the canonical map $\mathbf{G} \mathbf{L}_{Q_{(\mathcal{Z})}} \rightarrow$ $\mathbf{P G L} \mathbf{Q}_{(z)}$. The argument in [Ch, Thm. 3.1] shows that there is another closed embedding $\bar{S} \hookrightarrow \mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}}$, whose image will be denoted by $\bar{S}^{\prime}$, such that $[\lambda]$ is equivalent to some class $\left[\lambda^{\prime}\right] \in H^{1}\left(\mathcal{Z}, \bar{S}^{\prime}\right)$. Let $S^{\prime} \subset \mathbf{G} \mathbf{L}_{m, \mathcal{Z}}$ be the preimage of $\bar{S}^{\prime}$. Its centralizer $E^{\prime}$ in $Q_{(\mathcal{Z})}$ is a maximal commutative étale subalgebra of $Q_{(\mathcal{Z})}$ isomorphic to $E$. Since by the above lemma $E$ and $E^{\prime}$ are conjugate over $\mathcal{Z}$, so are the maximal tori $S, S^{\prime}$. This in turn implies the conjugacy of $\bar{S}$ and $\bar{S}^{\prime}$ in $\mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}}$. Thus the cocycle $\lambda^{\prime}$ is equivalent to some cocycle $\theta$ with coefficients in $\bar{S}$.

Assume for a moment that $E$ also admits an embedding into $Q_{(\mathcal{Z})}^{\prime}$. Then as above the group scheme $\mathbf{P G L}_{Q_{(\mathcal{Z})}^{\prime}}$ is a twisted from of $\mathbf{P G L} \mathbf{L}_{m, \mathcal{Z}}$ with some cocycle $\theta^{\prime}$ with coefficients in $\bar{S}$. Consider the exact sequence

$$
H^{1}(\mathcal{Z}, S)=1 \rightarrow H^{1}(\mathcal{Z}, \bar{S}) \rightarrow H^{2}\left(\mathcal{Z}, \mathbf{G}_{m, \mathcal{Z}}\right)=\operatorname{Br}(\mathcal{Z}) .
$$

The images of $[\theta]$ and $\left[\theta^{\prime}\right]$ in $\operatorname{Br}(\mathcal{Z})$ coincide, because the base change morphism $\operatorname{Br}(\mathcal{Z}) \hookrightarrow \operatorname{Br}(K)$ is injective and $Q_{(\mathcal{Z})}$ and $Q_{(\mathcal{Z})}^{\prime}$ are isomorphic over $K$. It follows that $[\theta]=\left[\theta^{\prime}\right]$ and this implies $Q_{(\mathcal{Z})} \simeq Q_{(\mathcal{Z})}^{\prime}$; in particular, $\xi_{i}=1$ as required.

To sum up: to finish the proof of Theorem 4.4 what is left to show is that $E$ admits an embedding in $Q_{(\mathcal{Z})}^{\prime}$, i.e., there exist elements $y_{1}, y_{3}, \ldots, y_{2 s-1} \in\left(Q_{(\mathcal{Z})}^{\prime}\right)^{\times}$ which commute and such that

$$
y_{1}^{\ell_{1}}=t_{1}, y_{3}^{\ell_{3}}=t_{3}, \ldots, y_{2 s-1}^{\ell_{s}}=t_{2 s-1} .
$$

Here the positive integers $\ell_{1}, \ldots, \ell_{s}$ and variables $t_{1}, \ldots, t_{n}$ are the same as in Example 1.8 applied to $Q$.

Fix a presentation $Q^{\prime}=\bigoplus_{\lambda \in \Lambda^{\prime}} k x^{\prime \lambda}$. As usual it induces a grading of $Q^{\prime}$. The isomorphism $f: \mathcal{A}_{(\mathcal{Z})}^{\prime} \rightarrow \mathcal{A}_{(\mathcal{Z})}$ induces an isomorphism

$$
\mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})}^{\prime}\right) \otimes_{\mathcal{Z}} K=\mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})}^{\prime} \otimes_{\mathcal{Z}} K\right) \rightarrow \mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})}\right) \otimes_{\mathcal{Z}} K=\mathrm{M}_{\ell}\left(Q_{(\mathcal{Z})} \otimes_{\mathcal{Z}} K\right)
$$

From the theory of central simple algebras over fields we know that the last implies that $Q_{(\mathcal{Z})}^{\prime} \otimes_{\mathcal{Z}} K \simeq Q_{(\mathcal{Z})} \otimes_{\mathcal{Z}} K$. Hence, there exist commuting elements $z_{1}, z_{3}, \ldots, z_{2 s-1} \in Q_{(\mathcal{Z})}^{\prime} \otimes_{\mathcal{Z}} K$ such that $z_{2 i-1}^{l_{i}}=t_{2 i-1}$ for all $i=1, \ldots, s$, where we view $t_{i} \in Q_{(\mathcal{Z})}^{\prime}$. Choose an element $r \in \mathcal{Z}$ such that $r z_{2 i-1} \in Q_{(\mathcal{Z})}^{\prime}$ for all $i$. Then

$$
\begin{equation*}
\left(r z_{2 i-1}\right)^{l_{i}}=r^{l_{i}} t_{2 i-1} . \tag{4.6.1}
\end{equation*}
$$

Recall that $Q_{(\mathcal{Z})}^{\prime}$ has a natural grading transferred from $Q^{\prime}$.
Let $u_{2 i-1}$ (resp. a) be the highest homogeneous component of $r z_{2 i-1}$ (resp. $r$ ) with respect to any order on $\Lambda$. Taking the highest components on the left and on the right in (4.6.1) we get $\left(u_{2 i-1}\right)^{l_{i}}=a^{l_{i}} t_{2 i-1}$. Note that $a$ is some monomial in the centre $\mathcal{Z}^{\times}$of $Q_{(\mathcal{Z})}^{\prime}$, hence it commutes with $u_{2 i-1}$. Then the elements

$$
y_{2 i-1}=a^{-1} u_{2 i-1} \in\left(Q_{(\mathcal{Z})}^{\prime}\right)^{\times}, i=1,3, \ldots, 2 s-1
$$

have the required properties.
4.7. Corollary. Let $\mathcal{L}=\mathfrak{s l}_{\ell}(Q)$ and $\mathcal{L}^{\prime}=\mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)$ where $Q$ and $Q^{\prime}$ are fgc quantum tori over a field of very good characteristic, let $\mathfrak{m} \subset \mathfrak{s l}_{\ell}(Q)\left(\right.$ resp. $\left.\mathfrak{m}^{\prime} \subset \mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)\right)$ be the MAD consisting of diagonal matrices with entries in $F$, and let $f: \mathcal{L}^{\prime} \rightarrow \mathcal{L}$ be an F-linear isomorphism of Lie algebras. Then $f\left(\mathfrak{m}^{\prime}\right)$ is conjugate to $\mathfrak{m}$.

Proof. This follows by combining Theorem 4.3 and Theorem 4.4.

## 5. Specialization of quantum tori

Our main method of dealing with non-fgc quantum tori is specialization which we develop in this section. In this section $k$ denotes a field of characteristic 0 .
5.1. Proposition. Let $\mathcal{F}$ be a finite subset of a field $k$ of characteristic 0 consisting of non-zero elements and let $\ell \in \mathbb{N}_{+}$. Then there exists a finitely generated subring $R \subset k$ and a maximal ideal $\mathfrak{m} \triangleleft R$ such that
(a) $\mathcal{F} \subset R \backslash \mathfrak{m}$, and
(b) $R / \mathfrak{m}$ is a finite field of characteristic $p>\ell$.

Proof. We can assume that $f^{-1} \in \mathcal{F}$ for every $f \in \mathcal{F}$. Let $R=\mathbb{Z}[\mathcal{F}] \subset k$ (resp. $C=\mathbb{Q}[\mathcal{F}] \subset k$ ) be the $\mathbb{Z}$-subalgebra (resp. $\mathbb{Q}$-subalgebra) generated by $\mathcal{F}$. By the Noether Normalization Lemma there exist algebraically independent $u_{1}, \ldots, u_{s} \in C$ over $\mathbb{Q}$ such that $C$ is integral over its subring $\mathbb{Q}\left[u_{1}, \ldots, u_{s}\right]$ and of finite type as a $\mathbb{Q}\left[u_{1}, \ldots, u_{s}\right]$-module, say with generators $c_{1}, \ldots, c_{t}$.

Observation. For finitely many polynomials $q_{1}, \ldots, q_{m} \in \mathbb{Q}\left[u_{1}, \ldots, u_{s}\right]$ there exists $n \in \mathbb{N}_{+}$such that $q_{1}, \ldots, q_{m} \in \mathbb{Z}[1 / n]\left[u_{1}, \ldots, u_{s}\right]$ (here $\mathbb{Z}[1 / n]$ is the localization of $\mathbb{Z}$ in $\left\{n^{a}: a \in \mathbb{N}\right\}$ ).

Apply this observation to the coefficients of the minimal polynomials of the integral elements $c_{1}, \ldots, c_{t}$ and to the coefficients appearing in the linear combinations expressing the elements of $\mathcal{F}$ in $\sum_{i=1}^{t} \mathbb{Q}\left[u_{1}, \ldots, u_{s}\right] c_{i}$. This yields that there exists $n \in \mathbb{N}_{+}$such that
(1) all coefficients of the minimal polynomials of the elements $c_{1}, \ldots, c_{t}$ belong to $E:=\mathbb{Z}[1 / n]\left[u_{1}, \ldots, u_{s}\right]$ and
(2) $R:=\mathbb{Z}[\mathcal{F}] \subset E\left[c_{1}, \ldots, c_{t}\right]=: D \subset C=\mathbb{Q}[\mathcal{F}]$.

Because of (1), each $c_{i}$ is integral over $E$, whence $D / E$ is an integral extension of finite type. Now choose a prime number $p$ such that $p \nmid n$ and $p>\ell$. The ideal $\mathfrak{p} \triangleleft E$, generated by $p$ and the $u_{1}, \ldots, u_{s}$, has the property that $E / \mathfrak{p} \simeq \mathbb{Z}[1 / n] /\langle p\rangle$, where $\langle p\rangle=p \mathbb{Z}[1 / n] \subset \mathbb{Z}[1 / n]$ is the ideal generated by $p$, whence $\langle p\rangle \subset \mathbb{Z}[1 / n]$ and therefore also $\mathfrak{p} \subset E$ are maximal ideals. Since $D$ is integral over $E$, there exists a maximal ideal $\mathfrak{n} \triangleleft D$ lying over $\mathfrak{p} \triangleleft E$. By construction, $D / \mathfrak{n}$ is a finite field of characteristic $p$. Recall $R \subset D$, and put $\mathfrak{m}=R \cap \mathfrak{n}$. Then $R / \mathfrak{m} \hookrightarrow D / \mathfrak{n}$. So $R / \mathfrak{m}$ is a finite subring of the field $D / \mathfrak{n}$, whence a field itself. It remains to observe that $f \notin \mathfrak{m}$ for every $f \in \mathcal{F}$ because $f$ is a unit in $D$.
5.2. Corollary. Let $Q$ be a quantum torus over a field $k$ of characteristic 0 , let $q=$ $\left(q_{i j}\right) \in \mathrm{M}_{n}(k)$ be the quantum matrix associated with a coordinatization of $Q$ and write $Q=\bigoplus_{\lambda \in \Lambda} k x^{\lambda}$ as in (1.2.1). Further, let $a_{1}, \ldots, a_{t} \in k \backslash\{0\}, b_{1}, \ldots, b_{m} \in Q$ be non-zero elements and let $g_{1}, \ldots, g_{p} \in \mathrm{M}_{\ell}(Q)$ be non-zero matrices.

Then there exists a finitely generated subring $R<k$ and a maximal ideal $\mathfrak{m} \triangleleft R$ with the following properties:
(i) All $a_{i}$ and $q_{i j} \in R$, all $b_{1}, \ldots, b_{m}$ lie in the unital graded subalgebra $\mathcal{A}=$ $\bigoplus_{\lambda \in \Lambda} R x^{\lambda}$ of $Q$, and all $g_{1}, \ldots, g_{p} \in \mathrm{M}_{\ell}(\mathcal{A})$.
(ii) Denoting by ${ }^{-}$the canonical quotient map, we have
(a) $\bar{R}=R / \mathfrak{m}$ is a finite field of very good characteristic $p>0$ for $\mathfrak{s l}_{\ell}(\overline{\mathcal{A}})$;
(b) all $\bar{a}_{i}$ and $\bar{q}_{i j} \in \bar{R}$ are non-zero, hence roots of unity;
(c) $\overline{\mathcal{A}}=\bigoplus_{\lambda \in \Lambda} \bar{R} x^{\lambda}$ is an fgc quantum torus over $\bar{R}$ with quantum matrix $\left(\bar{q}_{i j}\right)$ and $p \times[\overline{\mathcal{A}}: \mathcal{Z}(\overline{\mathcal{A}})]$;
(d) all $\bar{b}_{i} \neq 0$ in $\overline{\mathcal{A}}$;
(e) all $\bar{g}_{i}$ are non-zero in $\mathrm{M}_{\ell}(\overline{\mathcal{A}})$.

Proof. Let $\mathcal{F}$ be the finite subset of $k$ consisting of all $a_{i}, q_{i j}$, all non-zero $k$ coefficients of $b_{1}, \ldots, b_{m}$ and $g_{1}, \ldots, g_{p}$ and their inverses (the $k$-coefficients are taken with respect to a natural $k$-basis of $Q$ and $\mathrm{M}_{\ell}(Q)$ ). Let $R$ and $\mathfrak{m}$ be as in Proposition 5.1. Then all claims follow immediately from $\mathcal{F} \subset R \backslash \mathfrak{m}$.
5.3. Lemma. Let $Q$ be a quantum torus over a field $k$ of characteristic 0 . Then the Lie algebra $\mathfrak{s l}_{\ell}(Q)$ is finitely generated over $k$.

Proof. This fact is known for all Lie tori ([Ne1, Thm. 5]). In our concrete case, it can be proven as follows. We fix a parametrization $Q=\bigoplus_{\alpha \in \mathbb{Z}^{n}} k x^{\lambda}$; in particular this gives us coordinates $x_{i}, 1 \leq i \leq n$ corresponding to the standard basis of $\mathbb{Z}^{n}$. It is straightforward to check that $\mathfrak{s l}_{\ell}(Q)$ is generated by $\left\{E_{i j}, x_{p}^{ \pm 1} E_{i j}: 1 \leq i \neq\right.$ $j \leq \ell\}$.

We have seen in $1.2(\mathrm{f})$ that a quantum torus is fgc if for one coordinatization, equivalently for all coordinatizations, the entries of the associated quantum matrix are roots of unity. Hence, in a coordinatization of a non-fgc quantum torus with quantum matrix $q=\left(q_{i j}\right)$ at least one of the $q_{i j}$ is not a root of unity.
5.4. Theorem. Let $Q=\bigoplus_{\lambda \in \Lambda} k x^{\lambda}$ and $Q^{\prime}=\bigoplus_{\lambda^{\prime} \in \Lambda^{\prime}} k y^{\lambda^{\prime}}$ be non-fgc quantum tori over a field $k$ of characteristic 0 with associated quantum matrices $q=\left(q_{i j}\right) \in$ $\mathrm{M}_{n}(k)$ and $q^{\prime}=\left(q_{i j}^{\prime}\right) \in \mathrm{M}_{n^{\prime}}(k)$. We assume that we are given:

- non-zero elements $b_{1}, \ldots, b_{m} \in Q$ and non-zero elements $b_{1}^{\prime}, \ldots, b_{m}^{\prime} \in Q^{\prime}$;
- non-zero elements $g_{1}, \ldots, g_{s} \in \mathfrak{g l}_{\ell}(Q)$, and non-zero elements $g_{1}^{\prime}, \ldots, g_{s^{\prime}}^{\prime} \in$ $\mathfrak{g l}_{\ell^{\prime}}\left(Q^{\prime}\right) ;$
- a k-linear isomorphism $f: \mathfrak{s l}_{\ell}(Q) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)$ of Lie algebras.

Then there exists a subring $R<k$ and a maximal ideal $\mathfrak{m} \triangleleft R$ with the following properties:
(i) all $q_{i j} \in R$ and all $q_{i j}^{\prime} \in R$;
(ii) all $b_{1}, \ldots, b_{m}$ lie in the unital graded subalgebra $\mathcal{A}=\bigoplus_{\lambda \in \Lambda} R x^{\lambda}$ of $Q$, and all $g_{1}, \ldots, g_{s}$ are in $\mathfrak{g l}_{\ell}(\mathcal{A})$;
(iii) all $b_{1}^{\prime}, \ldots, b_{m}^{\prime}$ lie in the unital graded subalgebra $\mathcal{A}^{\prime}=\bigoplus_{\lambda^{\prime} \in \Lambda^{\prime}} R y^{\lambda^{\prime}}$ of $Q^{\prime}$, and all $g_{1}^{\prime}, \ldots, g_{s^{\prime}}^{\prime} \in \mathfrak{g l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$;
(iv) $f\left(\mathfrak{s l}_{\ell}(\mathcal{A})\right)=\mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$.
(v) Denoting by ${ }^{-}$the canonical quotient map, we have
(a) $\bar{R}=R / \mathfrak{m}$ is a finite field of very good characteristic for $\mathfrak{s l}_{\ell}(\overline{\mathcal{A}})$ and $\mathfrak{s l}_{\ell^{\prime}}(\overline{\mathcal{A}})$;
(b) all $\bar{q}_{i j}, \bar{q}_{i j}^{\prime} \in \bar{R}$ are non-zero, hence roots of unity;
(c) $\overline{\mathcal{A}}=\mathcal{A} / \mathfrak{m} \mathcal{A}=\bigoplus_{\lambda \in \Lambda} \bar{R} x^{\lambda}$ and $\overline{\mathcal{A}}^{\prime}=\bigoplus_{\lambda^{\prime} \in \Lambda^{\prime}} \bar{R} y^{\lambda^{\prime}}$ are fgc quantum tori over $\bar{R}$ with associated quantum matrices $\left(\bar{q}_{i j}\right)$ and $\left(\bar{q}_{i j}^{\prime}\right)$;
(d) $\bar{f}: \mathfrak{s l}_{\ell}(\overline{\mathcal{A}}) \rightarrow \mathfrak{s l}_{\ell^{\prime}}\left(\overline{\mathcal{A}}^{\prime}\right)$ is an $\bar{R}$-isomorphism of the corresponding Lie $\bar{R}$-algebras;
(e) all $\bar{b}_{i}$ are non-zero in $\overline{\mathcal{A}}$ and all $\bar{b}_{i}^{\prime}$ are non-zero in $\overline{\mathcal{A}}^{\prime}$;
(f) all $\bar{g}_{i}$ are non-zero in $\mathfrak{g l}_{\ell}(\overline{\mathcal{A}})$ and all $\bar{g}_{i}^{\prime}$ are non-zero in $\mathfrak{g l}_{\ell^{\prime}}\left(\overline{\mathcal{A}}^{\prime}\right)$.

Proof. By definition, the coordinates of $0 \neq b \in Q$ are the non-zero $s_{\lambda} \in k$ when $b$ is written as $b=\sum_{\lambda \in \Lambda} s_{\alpha} x^{\lambda}$. The coordinates of $0 \neq g=\sum_{i, j} g_{i j} E_{i j} \in \mathrm{M}_{\ell}(Q)$ are the coordinates of the non-zero $g_{i j} \in Q$. The coordinates of $0 \neq b^{\prime} \in Q^{\prime}$ and $0 \neq g^{\prime} \in \mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)$ are defined analogously. We choose finite generating systems $S \subset \mathfrak{s l}_{\ell}(Q)$ and $S^{\prime} \subset \mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right)$ as in Lemma 5.3, and put $g=f^{-1}$. We let $\mathcal{F} \subset k$ consist of

- all $q_{i j}, q_{i j}^{\prime}$, the coordinates of all $b_{i}, b_{i}^{\prime}, g_{i}, g_{i}^{\prime}$ together with their inverses,
- the elements $\left(q_{i j}-1\right)^{-1}$ and $\left(q_{i j}^{\prime}-1\right)^{-1}$ whenever $q_{i j}$ or $q_{i j}^{\prime}$ is not a root of unity, and
- the coefficients of all elements in $f(S)$ and $g\left(S^{\prime}\right)$.

We now apply Proposition 5.1 for this $\mathcal{F}$ but with the $\ell$ there replaced by $\max \left\{\ell, \ell^{\prime}\right\}$. This provides us with $(R, \mathfrak{m})$ as required in the Theorem. Indeed, by construction we have $f\left(\mathfrak{s l}_{\ell}(\mathcal{A})\right) \subset \mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ and similarly $g\left(\mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)\right) \subset \mathfrak{s l}_{\ell}(\mathcal{A})$. It follows that $f\left(\mathfrak{s l}_{\ell}(\mathcal{A})\right)=\mathfrak{s l}_{\ell^{\prime}}\left(\mathcal{A}^{\prime}\right)$ (because $g$ is the inverse for $f$ ), so that (iv) holds. The remaining claims follow immediately from $\mathcal{F} \subset R \backslash \mathfrak{m}$.

## 6. Some preliminaries for Step 3 of the proof of the main theorem

### 6.1. Setting I

In this section we use the following setting:

- $Q$ is a quantum torus over a field $F$ with grading group $\Lambda \simeq \mathbb{Z}^{n}$;
- We fix a basis $\varepsilon$ of $\Lambda$; the $\varepsilon$-trace, the corresponding $\mathbb{Z}$-grading, and the $\varepsilon$-degree will all be taken with respect to the fixed $\varepsilon$. We will therefore simply write $\operatorname{deg}$ instead of $\operatorname{deg}_{\varepsilon}$. We identify $\Lambda=\mathbb{Z}^{n}$ via $\varepsilon$, and define $\Lambda^{+}=\mathbb{N}^{n} \subset \mathbb{Z}^{n}$.
- Corresponding to $\varepsilon$ there exists a coordinatization of $Q$ as $Q=\bigoplus_{\lambda \in \mathbb{Z}^{n}} F x^{\lambda}$. We let $0 \neq x_{i} \in Q$ denote the element that corresponds to the $i$ th basis vector $\varepsilon_{i}$ in $\varepsilon$, and put $Q^{+}=\bigoplus_{\lambda \in \Lambda^{+}} Q^{\lambda}$. Note that $Q^{+}$is a unital subring of $Q$.
- For $\ell \geq 2$ we let $V$ be a free right $Q$-module of rank $\ell$. We fix a basis $e_{1}, \ldots e_{n}$ of $V$ so that we can write $V=\bigoplus_{i=1}^{\ell} e_{i} Q$. We put $V^{+}=\bigoplus_{i=1}^{\ell} e_{i} Q^{+}$.
- We say that $x_{i}$ divides $q \in Q^{+}$if every $\lambda \in \operatorname{supp}(q)$ has the form $\lambda=$ $\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ with respect to $\varepsilon$ and $\lambda_{i}>0$. In this case $q x_{i}^{-1} \in Q^{+}$.
- Any $0 \neq v \in V$ can be uniquely written as $v=\sum_{i=1}^{\ell} e_{i} q_{i}$ with $q_{i} \in Q$. We put

$$
\operatorname{deg}(v)=\max \left\{\operatorname{deg}\left(q_{i}\right): q_{i} \neq 0\right\}
$$

We refer to the $q_{i}$ as the coordinates of $v$.
6.2. Lemma. Let $0 \neq v \in V$ and let $0 \neq q \in Q$. Then $v q \neq 0$ and

$$
\operatorname{deg}(v q)=\operatorname{deg}(v)+\operatorname{deg}(q)
$$

Proof. We write $v=\sum_{i=1}^{\ell} e_{i} q_{i}$ as above. The first claim is obvious: $q_{i} q \neq 0 \Longleftrightarrow$ $q_{i} \neq 0$, and at least one coordinate $q_{i} \neq 0$. For the non-zero $q_{i}$ we have $\operatorname{deg}\left(q_{i} q\right)=$ $\operatorname{deg}\left(q_{i}\right)+\operatorname{deg}(q)$ by (1.3.3). Hence, if for simpler notation $\operatorname{deg}(v)=\operatorname{deg}\left(q_{1}\right)$ then $\operatorname{deg}\left(q_{i} q\right) \leq \operatorname{deg}\left(q_{1} q\right)$ for all $i$ with $q_{i} \neq 0$.

### 6.3. Setting II

We continue with the Setting of 6.1. In addition, we fix a non-zero $Q$-submodule $U \subset V$, and put $U^{+}=U \cap V^{+}$. Observe $U^{+} \neq\{0\}$ since $q Q \cap Q^{+} \neq\{0\}$ for any $0 \neq q \in Q$. Since $\operatorname{deg}(u) \geq 0$ for every $0 \neq u \in U^{+}$there exist minimal vectors $u_{0} \in U^{+}$such that

$$
\operatorname{deg}\left(u_{0}\right) \leq \operatorname{deg}(u) \quad \text { for all } 0 \neq u \in U^{+}
$$

We call $u \in U^{+}$indivisible if $u \neq 0$ and the coordinates of $u$ do not have a common divisor $x_{i}, 1 \leq i \leq n$, in $Q^{+}$. It is obvious that indivisible vectors exist.

Moreover,

$$
\text { every minimal vector } u_{0} \in U^{+} \text {is indivisible. }
$$

Indeed, write $u_{0}=\sum_{j=1}^{\ell} e_{j} q_{j}$ with all $q_{j} \in U^{+}$. Assume that all $q_{j}$ are divisible by some $x_{i}$. Then $0 \neq u_{0} x_{i}^{-1}=\sum_{j=1}^{\ell} e_{j} q_{j} x_{i}^{-1} \in U^{+}$since all $q_{j} x_{i}^{-1} \in Q^{+}$. But $\operatorname{deg}\left(u_{\text {min }} x_{i}^{-1}\right)=\operatorname{deg}\left(u_{0}\right)+\operatorname{deg}\left(x_{i}^{-1}\right)=\operatorname{deg}\left(u_{0}\right)-1<\operatorname{deg}\left(u_{0}\right)$, a contradiction.
6.4. Lemma. Assume Setting 6.3, and let $u_{0} \in U^{+}$be indivisible, and let $q \in Q$. Then

$$
u_{0} q \in U^{+} \Longleftrightarrow q \in Q^{+}
$$

Proof. We only need to show that the left-hand side implies the right-hand side. We reason by contradiction. Assume $q \notin Q^{+}$. We write $u_{0}=\sum_{j=1}^{\ell} e_{j} q_{j}$ with all $q_{j} \in Q^{+}$. We choose a minimal $\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right) \in \Lambda^{+}$such that $q x^{\lambda} \in Q^{+}$. Here "minimal" means that $q x^{\lambda} x_{i}^{-1} \notin Q^{+}$for all $i$. Since $q \notin Q^{+}$, some $\lambda_{i}>0$. Let $I$ be the ideal of the ring $Q^{+}$generated by $x_{i}$. Note $I=x_{i} Q^{+}=Q^{+} x_{i}$. By definition of an indivisible element, at least one of the coordinate $q_{j}$ of $u_{0}$ is not divisible by $x_{i}$ in $Q^{+}$(for $i$ with $\lambda_{i}>0$ ). To simplify notation, assume this is $q_{1}$, i.e., $q_{1} \notin I$. Then the following holds.
(i) $q x^{\lambda} \notin I$. Otherwise, $q x^{\lambda}=q^{\prime} x_{i}$ for some $q^{\prime} \in Q^{+}$, whence $q x^{\lambda} x_{i}^{-1} \in Q^{+}$, and so $q x^{\mu} \in Q^{+}$for $\mu=\lambda-\varepsilon_{i} \in \Lambda^{+}$.
(ii) $q_{1} q x^{\lambda} \in Q^{+}$because $q_{1} \in Q^{+}$and $q x^{\lambda} \in Q^{+}$. Furthermore, $x^{\lambda} \in I$ because $\lambda_{i}>0$. Hence $q_{1} q x^{\lambda} \in I$. Thus $x_{1} \mid q_{1} q x^{\lambda}$, but $x_{1} \not\left\langle q_{1}\right.$ and $x_{1} \not \backslash q x^{\lambda}$. This contradicts (iii) below.
(iii) $Q^{+} / I$ is a subring of the quantum torus with associated quantum matrix $q^{\prime}=\left(q_{i j}\right)$ where $2 \leq i, j \leq n$. It is therefore a domain.

Our assumption $q \notin Q^{+}$has thus led to a contradiction.
6.5. Corollary. Let $u_{0} \in U^{+}$be an indivisible vector. Then

$$
U=u_{0} Q \quad \Longleftrightarrow \quad U^{+}=u_{0} Q^{+}
$$

Proof. If $U=u_{0} Q$ and $u^{+} \in U^{+}$, then $u^{+}=u_{0} q$ with $q \in Q$ and Lemma 6.4 shows $q \in Q^{+}$. Conversely, if $U^{+}=u_{0} Q^{+}$and $u \in U$ is arbitrary, we can take $x^{\lambda} \in Q$ such that $u x^{\lambda} \in U^{+}$, whence $u x^{\lambda}=u_{0} q$ for some $q \in Q^{+}$. But then $u=u_{0} q\left(x^{\lambda}\right)^{-1} \in u_{0} Q$.
6.6. Lemma. In addition to the Setting 6.3 assume that $U$ admits a complement: $V=U \oplus U^{\prime}$ for some $Q$-subspace $U^{\prime}$. Let $u_{0} \in U^{+}$be a minimal vector and put $Q^{++}=\bigoplus_{\lambda \in \mathbb{N}^{n} \backslash\{0\}} Q^{\lambda}$. Then $u_{0} \notin v\left(Q^{++}\right)$for any $v \in V^{+}$.
Proof. Assume to the contrary that $u_{0}=v q$ for some $q \in Q^{++}$and $v \in V^{+}$. Decompose $v=u+u^{\prime}$ with $u \in U$ and $u^{\prime} \in U^{\prime}$. Then $u_{0}=u q+u^{\prime} q$ shows $u^{\prime} q=0$. So without loss of generality we can assume $v \in U^{+}$. Now apply Lemma 6.2 to get

$$
\operatorname{deg}(v)+\operatorname{deg}(q)=\operatorname{deg}(v q)=\operatorname{deg}\left(u_{0}\right) \leq \operatorname{deg}(v)
$$

(because $u_{0}$ is minimal) and hence $\operatorname{deg}(q)=0$, i.e., $q \in F^{\times} \cdot 1_{F}$, a contradiction.

## 7. Proof of the main theorem

### 7.1. Setting and plan of the proof

Throughout this section, $k$ is a base field of characteristic 0 and $Q$ and $Q^{\prime}$ are non-fgc quantum tori. We assume that they are coordinatized as

$$
Q=\bigoplus_{\lambda \in \Lambda} k x^{\lambda} \quad \text { and } \quad Q^{\prime}=\bigoplus_{\lambda^{\prime} \in \Lambda^{\prime}} k y^{\lambda^{\prime}}
$$

for $\Lambda=\mathbb{Z}^{n}$ and $\Lambda^{\prime}=\mathbb{Z}^{n^{\prime}}$ with associated quantum matrices $q=\left(q_{i j}\right) \in \mathrm{M}_{n}(k)$ and $q^{\prime}=\left(q_{i j}^{\prime}\right) \in \mathrm{M}_{n^{\prime}}(k)$. We assume that

$$
f: \mathfrak{s l}_{\ell^{\prime}}\left(Q^{\prime}\right) \rightarrow \mathfrak{s l}_{\ell}(Q)
$$

is a $k$-linear isomorphism. We apply Lemma 2.5 to extend $f$ to an isomorphism

$$
f_{\mathfrak{g l}}: \mathfrak{g l}_{\ell^{\prime}}\left(Q^{\prime}\right) \rightarrow \mathfrak{g l}_{\ell}(Q)
$$

In the first step of the proof (Proposition 7.2) we will show $\ell=\ell^{\prime}$. Next, it will follow from Proposition 7.3 that we may assume that

$$
\left.\phi=f_{\mathfrak{g} r}: \mathrm{M}_{\ell}\left(Q^{\prime}\right)\right) \rightarrow \mathrm{M}_{\ell}(Q)
$$

is an isomorphism of associative algebras. In the final step of the proof we will establish that if $\mathfrak{h}^{\prime} \subset \mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)$ (resp. $\left.\mathfrak{h} \subset \mathrm{M}_{\ell}(Q)\right)$ is the standard MAD of $\mathrm{M}_{\ell^{\prime}}\left(Q^{\prime}\right)$ (resp. $\left.\mathrm{M}_{\ell}(Q)\right)$ then $\phi\left(\mathfrak{h}^{\prime}\right)$ is conjugate to $\mathfrak{h}$ by an element of $\mathrm{GL}_{\ell}(Q)$.
7.2. Proposition. In the setting 7.1 we have $\ell=\ell^{\prime}$.

Proof. According to Theorem 5.4 there exist a subring $R \subset k$ and a maximal ideal $\mathfrak{m} \triangleleft R$ such that $f$ induces an $\bar{R}$-isomorphism

$$
\bar{f}: \mathfrak{s l}_{\ell^{\prime}}\left(\overline{\mathcal{A}}^{\prime}\right) \rightarrow \mathfrak{s l}_{\ell}(\overline{\mathcal{A}}) .
$$

Since $\overline{\mathcal{A}}$ and $\overline{\mathcal{A}}^{\prime}$ are quantum tori over $\bar{R}$ of fgc type, by Theorem 4.3 we have $\ell=\ell^{\prime}$.

### 7.3. Proposition. Consider the following two maps:

(a) $f_{\mathfrak{g l}}: \mathfrak{g l}_{\ell}\left(Q^{\prime}\right) \rightarrow \mathfrak{g l}_{\ell}(Q)$,
(b) the extension of $f \circ \iota^{\mathrm{op}}: \mathfrak{s l}_{\ell}\left(\left(Q^{\prime}\right)^{\mathrm{op}}\right) \rightarrow \mathfrak{s l}_{\ell}(Q)$ to a Lie algebra isomorphism

Then one of these maps is an isomorphism of the underlying associative $k$-algebras. Proof. Assume the contrary. Then there exist $g_{1}, g_{2}, g_{3}, g_{4} \in \mathrm{M}_{\ell}\left(Q^{\prime}\right)$ such that

$$
f_{\mathfrak{g r}}\left(g_{1} g_{2}\right) \neq f_{\mathfrak{g r}}\left(g_{1}\right) f_{\mathfrak{g r}}\left(g_{2}\right) \quad \text { and } \quad f_{\mathfrak{g r}}\left(-g_{3} g_{4}\right) \neq f_{\mathfrak{g r}}\left(g_{4}\right) f_{\mathfrak{g r}}\left(g_{3}\right) .
$$

Put

$$
g_{1}^{\prime}=f_{\mathfrak{g r}}\left(g_{1} g_{2}\right), g_{2}^{\prime}=f_{\mathfrak{g r}}\left(g_{1}\right), g_{3}^{\prime}=f_{\mathfrak{g r}}\left(g_{2}\right), g_{4}^{\prime}=g_{1}^{\prime}-g_{2}^{\prime} g_{3}^{\prime}
$$

and similarly

$$
g_{5}^{\prime}=f_{\mathfrak{g r}}\left(-g_{3} g_{4}\right), g_{6}^{\prime}=f_{\mathfrak{g r}}\left(g_{3}\right), g_{7}^{\prime}=f_{\mathfrak{g r}}\left(g_{4}\right), g_{8}^{\prime}=g_{5}^{\prime}-g_{7}^{\prime} g_{6}^{\prime}
$$

Recall that by Lemma 2.3 one has the decomposition

$$
\mathfrak{g l}_{\ell}(Q)=\mathcal{Z}(Q) E_{\ell} \oplus \mathfrak{s l}_{\ell}(Q)
$$

and similarly

$$
\mathfrak{g l}_{\ell}\left(Q^{\prime}\right)=\mathcal{Z}\left(Q^{\prime}\right) E_{\ell} \oplus \mathfrak{s l}_{\ell}\left(Q^{\prime}\right)
$$

So every element $g_{i}$ (resp. $g_{i}^{\prime}$ ) can be written as the sum $g_{i}=q_{i} E_{\ell}+\tilde{g}_{i}$ (resp. $\left.g_{i}^{\prime}=q_{i}^{\prime} E_{\ell}+\tilde{g}_{i}^{\prime}\right)$ where $q_{i}\left(\right.$ resp. $\left.q_{i}^{\prime}\right)$ is in the centre of $Q$ (resp. $\left.Q^{\prime}\right)$ and $\tilde{g}_{i}\left(\right.$ resp. $\left(\tilde{g}_{i}^{\prime}\right)$ is a sum of commutators of elements of $\mathfrak{g l}_{\ell}(Q)$ (resp. $\left.\mathfrak{g l}_{\ell^{\prime}}\left(Q^{\prime}\right)\right)$. We add to our list of elements $g_{1}, \ldots, g_{4}$ (resp. $g_{1}^{\prime}, \ldots, g_{8}^{\prime}$ ) all their components arising in the above two decompositions (including elements appearing in the writing of $\tilde{g}_{i}, \tilde{g}_{i}^{\prime}$ as sums of commutators).

We now apply Theorem 5.4 with these data. This provides us with a subring $R \subset k$ and a maximal ideal $\mathfrak{m} \triangleleft R$ satisfying the many conclusions of loc. cit. In particular, denoting by

$$
f_{\mathcal{A}}: \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\prime}\right) \rightarrow \mathfrak{s l}_{\ell}(\mathcal{A})
$$

the isomorphism obtained by restriction of $f$, we have an isomorphism

$$
\bar{f}_{\mathcal{A}}: \mathfrak{s l}_{\ell}\left(\overline{\mathcal{A}}^{\prime}\right) \rightarrow \mathfrak{s l}_{\ell}(\overline{\mathcal{A}})
$$

where now both $\overline{\mathcal{A}}^{\prime}$ and $\overline{\mathcal{A}}$ are fgc quantum tori over the finite field $R / \mathfrak{m}$ of very good characteristic. This allows us to apply Theorem 4.3. In view of Remark 2.6 we get that either

$$
\left(\bar{f}_{\mathcal{A}}\right)_{\mathfrak{g l}}: \mathfrak{g l}_{\ell}\left(\overline{\mathcal{A}}^{\prime}\right) \rightarrow \mathfrak{g l}_{\ell}(\overline{\mathcal{A}}) \quad \text { or } \quad\left(\bar{f}_{\mathcal{A}} \circ \iota^{\mathrm{op}}\right)_{\mathfrak{g r}}: \mathfrak{g l}_{\ell}\left(\overline{\mathcal{A}}^{\prime \mathrm{op}}\right) \rightarrow \mathfrak{g l}_{\ell}(\overline{\mathcal{A}})
$$

is an isomorphism of the underlying associative algebras.

On the other side, arguing as in Lemma 2.5 we get the following: if $\mathcal{Z}(\mathcal{A})$ (resp. $\left.\mathcal{Z}\left(\mathcal{A}^{\prime}\right)\right)$ denotes the centre of $\mathcal{A}$ (resp. $\mathcal{A}^{\prime}$ ) our map $f_{\mathcal{A}}$ has a canonical extension to

$$
\mathcal{Z}\left(\mathcal{A}^{\prime}\right) E_{\ell} \oplus \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\prime}\right) \rightarrow \mathcal{Z}(\mathcal{A}) E_{\ell} \oplus \mathfrak{s l}_{\ell}(\mathcal{A})
$$

which abusing notation we will still denote by $\left(f_{\mathcal{A}}\right)_{\mathfrak{g} r}$. Note that $\left(f_{\mathcal{A}}\right)_{\mathfrak{g} r}$ coincides with the restriction of $f_{\mathfrak{g r}}$ to $\mathcal{Z}\left(\mathcal{A}^{\prime}\right) E_{\ell} \oplus \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\prime}\right)$ and that by our construction all matrices $q_{i} E_{\ell}, q_{i}^{\prime} E_{\ell^{\prime}}, g_{i}^{\prime}$ and $g_{i}$ live in $\mathcal{Z}\left(\mathcal{A}^{\prime}\right) E_{\ell} \oplus \mathfrak{s l}_{\ell}\left(\mathcal{A}^{\prime}\right)$ and $\mathcal{Z}(\mathcal{A}) E_{\ell} \oplus \mathfrak{s l}_{\ell}(\mathcal{A})$. Passing to the residues we get an isomorphism

$$
\overline{\left(f_{\mathcal{A}}\right)_{\mathfrak{g r}}}: \overline{\mathcal{Z}\left(\mathcal{A}^{\prime}\right)} \oplus \mathfrak{s l}_{\ell}\left(\overline{\mathcal{A}}^{\prime}\right) \rightarrow \overline{\mathcal{Z}(\mathcal{A})} \oplus \mathfrak{s l}_{\ell}(\overline{\mathcal{A}}) .
$$

It is easily seen from the construction that

$$
\overline{\left(f_{\mathcal{A}}\right)_{\mathfrak{g r}}}=\left.\left(\left(\bar{f}_{\mathcal{A}}\right)_{\mathfrak{g r}}\right)\right|_{\overline{\mathcal{Z}\left(\mathcal{A}^{\prime}\right)} \oplus \mathfrak{s r}\left(\overline{\mathcal{A}}^{\prime}\right)}=: \psi .
$$

We now obtain a contradiction: In case $\left(\bar{f}_{\mathcal{A}}\right)_{\mathfrak{g} r}$ is an isomorphism of the underlying associative algebras we have

$$
\overline{g_{1}^{\prime}}=\psi\left(\overline{g_{1} g_{2}}\right)=\psi\left(\overline{g_{1}}\right) \psi\left(\overline{g_{2}}\right)=\overline{g_{2}^{\prime} g_{3}^{\prime}},
$$

whence

$$
\overline{g_{4}^{\prime}}=\overline{g_{1}^{\prime}-g_{2}^{\prime} g_{3}^{\prime}}=\overline{g_{1}^{\prime}}-\overline{g_{2}^{\prime} g_{3}^{\prime}}=0
$$

contradicting $\overline{g_{4}^{\prime}} \neq 0$ by Theorem 5.4. In the other case, one obtains a contradiction in the same way.

### 7.4. Final step

As indicated above, from now on we will assume that

$$
\phi: \mathrm{M}_{\ell}\left(Q^{\prime}\right) \rightarrow \mathrm{M}_{\ell}(Q)
$$

is an isomorphism of associative $k$-algebras. Let

$$
V=Q \oplus \ldots \oplus Q
$$

be the free right $Q$-module of rank $\ell$ defined in (2.2.4) for $\mathcal{A}=Q$. We know that $\mathrm{M}_{\ell}(Q)$ acts on $V$ from the left while $Q$ acts from the right. We denote by $\mathrm{B}=$ $\left\{e_{1}, \ldots, e_{\ell}\right\}$ the standard basis of the $Q$-module $V$, defined in (2.2.5). Furthermore, we know that $E_{i}^{\prime}=E_{i i}^{\prime} \in \mathrm{M}_{\ell}\left(Q^{\prime}\right), i=1, \ldots, \ell$ form a complete orthogonal system of idempotents in $\mathrm{M}_{\ell}\left(Q^{\prime}\right)$. Since $\phi$ preserves the associative multiplication, the image of the standard orthogonal system $\left(E_{11}^{\prime}, \ldots, E_{\ell \ell}^{\prime}\right)$ of $\mathrm{M}_{\ell}\left(Q^{\prime}\right)$ is a complete orthogonal system in $\mathrm{M}_{\ell}(Q)$. We put

$$
\widetilde{E}_{i}=\phi\left(E_{i i}^{\prime}\right) \in \mathrm{M}_{\ell}(Q), 1 \leq i \leq \ell
$$

We then know from Lemma 2.10 that $V$ decomposes with respect to $\left(\widetilde{E}_{1}, \ldots, \widetilde{E}_{\ell}\right)$ :

$$
V=V_{1} \oplus \cdots \oplus V_{\ell}, \quad \text { for } \quad V_{i}=\widetilde{E}_{i}(V)
$$

As shown in Lemma 2.10(c) conjugacy will follow once we know that all the $V_{i}$ are cyclic $Q$-modules. We will prove this using again specialization.

To simplify the notation we let $U=V_{i}$ for any one of the $i, 1 \leq i \leq \ell$. We can apply the results of $\S 6$ and choose a minimal vector $u_{0} \in U^{+}$. For $t \in \mathbb{N}$ define

$$
\begin{aligned}
P_{t} & =\left\{q \in Q^{+}: \operatorname{deg}(q) \leq t\right\} \\
V_{t} & =\left\{v \in V^{+}: \operatorname{deg}(v) \leq t\right\} \\
U_{t} & =V_{t} \cap U^{+}
\end{aligned}
$$

The spaces $P_{t}, V_{t}$ and $U_{t}$ are finite-dimensional $k$-vector spaces. We denote by $\mathbb{P}(\cdot)$ the corresponding projective spaces. Since $0 \neq q \Longrightarrow u_{0} q \neq 0$ we have a well-defined regular map

$$
\varphi_{t}: \mathbb{P}\left(P_{t}\right) \rightarrow \mathbb{P}\left(U_{t+\operatorname{deg}\left(u_{0}\right)}\right), \quad[q] \mapsto\left[u_{0} q\right]
$$

Its image is the zero set of a finite set $G_{t}$ of non-zero homogenous polynomials (in fact linear forms) with coefficients in $k$ :

$$
\operatorname{Im}\left(\varphi_{t}\right)=\operatorname{Zero}\left(G_{t}\right)
$$

Similarly, for $0 \leq s<\operatorname{deg}\left(u_{0}\right)$ we have a regular map

$$
\gamma_{s}: \mathbb{P}\left(V_{s}\right) \times \mathbb{P}\left(P_{\operatorname{deg}\left(u_{0}\right)-s}\right) \rightarrow \mathbb{P}\left(V_{\operatorname{deg}\left(u_{0}\right)}\right), \quad([v],[q]) \rightarrow[v q]
$$

Since we are dealing with projective spaces, the image of $\gamma_{s}$ is a closed subvariety, whence given by a finite set $H_{s}$ of non-zero homogeneous polynomials with coefficients in $k$ :

$$
\operatorname{Im}\left(\gamma_{s}\right)=\operatorname{Zero}\left(H_{s}\right)
$$

By Lemma 6.6, $\left[u_{0}\right] \notin \operatorname{Im}\left(\gamma_{s}\right)$ for all $0 \leq s<\operatorname{deg}\left(u_{0}\right)$. Hence:

$$
\begin{equation*}
h_{s}\left(u_{0}\right) \neq 0 \quad \text { for some } h_{s} \in H_{s}, 0 \leq s<\operatorname{deg}\left(u_{0}\right) . \tag{7.4.1}
\end{equation*}
$$

Recall that our goal is to show $U=u_{0} Q$, i.e., in view of Lemma 6.4: $U^{+}=u_{0} Q^{+}$. For the purpose of contradiction, assume this is not the case. Thus there exists $v_{0} \in U^{+} \backslash u_{0} Q^{+}$. Observe

$$
d:=\operatorname{deg}\left(v_{0}\right)-\operatorname{deg}\left(u_{0}\right) \geq 0
$$

Therefore $\left[v_{0}\right] \notin \operatorname{Im}\left(\varphi_{d}\right)$, i.e.,

$$
\begin{equation*}
g_{d}\left(v_{0}\right) \neq 0 \quad \text { for some } g_{d} \in G_{d} \tag{7.4.2}
\end{equation*}
$$

We now apply Corollary 5.2 to construct a subring $R<k$. The finitely many elements $a_{i} \in k, b_{i} \in Q$ and $g_{i} \in \mathrm{M}_{\ell}(Q)$ of loc. cit. are the following.

- in $k$ : the elements $h_{s}\left(u_{0}\right)$ and $g_{d}\left(v_{0}\right)$ of (7.4.1) and (7.4.2) respectively; all $q_{i j}$; the coefficients of the polynomial $g_{d}$ and of all polynomials in $H_{s}, 0 \leq$ $s<\operatorname{deg}\left(u_{0}\right)$;
- in $Q$ : the (by definition non-zero) coefficients of the vectors $u_{0}$ and $v_{0}$;
- in $\mathrm{M}_{\ell}(Q)$ : the matrices $\widetilde{E}_{i}, 1 \leq i \leq \ell$.

As in Corollary 5.2 let $\mathcal{A}=\bigoplus_{\lambda \in \Lambda} R x^{\lambda}$. We then have objects "over $R$ ":

$$
V_{\mathcal{A}}=\bigoplus_{i=1}^{\ell} e_{i} \mathcal{A}, \quad \mathcal{A}^{+}=\bigoplus_{\lambda \in \Lambda^{+}} R x^{\lambda}, \quad V_{\mathcal{A}}^{+}=\bigoplus_{i=1}^{\ell} e_{i} \mathcal{A}^{+}
$$

Since all matrices $\widetilde{E}_{i} \in \mathrm{M}_{\ell}(\mathcal{A})$ we get a decomposition

$$
V_{\mathcal{A}}=V_{\mathcal{A}, 1} \oplus \cdots \oplus V_{\mathcal{A}, \ell}, \quad V_{\mathcal{A}, i}=V_{\mathcal{A}} \cap V_{i} .
$$

In particular, $U_{\mathcal{A}}=U \cap V_{\mathcal{A}}$. We choose the maximal ideal $\mathfrak{m} \triangleleft R$ as in Corollary 5.2, and denote by ${ }^{-}$the quotient objects:

$$
\begin{aligned}
\bar{R} & =R / \mathfrak{m} & & \\
\overline{\mathcal{A}}=\mathcal{A} / \mathfrak{m} \mathcal{A} & =\bigoplus_{\lambda \in \Lambda} \bar{R} x^{\lambda}, & & \overline{\mathcal{A}}^{+}=\mathcal{A}^{+} / \mathfrak{m} \mathcal{A}^{+}=\bigoplus_{\lambda \in \Lambda^{+}} \bar{R} x^{\lambda} \\
\bar{V}_{\mathcal{A}}=V_{\mathcal{A}} / \mathfrak{m} V_{\mathcal{A}} & =\bigoplus_{i=1}^{\ell} e_{i} \overline{\mathcal{A}} \simeq \overline{\mathcal{A}}^{\ell}, & & \bar{V}_{\mathcal{A}}^{+}=V_{\mathcal{A}}^{+} / \mathfrak{m} V_{\mathcal{A}}^{+}=\bigoplus_{i=1}^{\ell} e_{i} \overline{\mathcal{A}}^{+} \simeq \overline{\mathcal{A}}^{\ell} \\
\bar{U}_{\mathcal{A}} & =U_{\mathcal{A}} / \mathfrak{m} U_{\mathcal{A}} . & &
\end{aligned}
$$

By construction, $\overline{\mathcal{A}}$ is an fgc quantum torus over the finite field $\bar{R}$ which has very good characteristic for $\mathfrak{s l}_{\ell}(\overline{\mathcal{A}})$. Hence, by Corollary 4.7, conjugacy holds in $\mathfrak{s l}_{\ell}(\overline{\mathcal{A}})$. Thus, by Lemma $2.10, \bar{U}_{\mathcal{A}}$ is a free $\overline{\mathcal{A}}$-module, say $\bar{U}_{\mathcal{A}}=\bar{c} \cdot \overline{\mathcal{A}}$. We can apply the results of $\S 6$ : without loss of generality, $\bar{c} \in \bar{U}_{\mathcal{A}}^{+}=\bar{U}_{\mathcal{A}} \cap \bar{V}_{\mathcal{A}}^{+}$. We can even assume that $\bar{c}$ is indivisible. Thus, by Corollary $6.5, \bar{U}_{\mathcal{A}}^{+}=\bar{c} \overline{\mathcal{A}}^{+}$. Since $\bar{u}_{0} \in \bar{U}_{\mathcal{A}}^{+}$we get from Lemma 6.4 that

$$
\bar{u}_{0}=\bar{c} \cdot \bar{a} \quad \text { for some } \bar{a} \in \overline{\mathcal{A}}^{+} .
$$

Our next goal is to show that $\bar{a} \in \bar{R} \cdot 1_{\overline{\mathcal{A}}}$. To this end we use the "bar"-versions of the vector spaces and maps defined above:

$$
\begin{gathered}
\bar{P}_{t}=\left\{q \in \overline{\mathcal{A}}^{+}: \operatorname{deg}(\bar{q}) \leq t\right\}, \quad \bar{V}_{t}=\left\{\bar{v} \in \bar{V}_{\mathcal{A}}^{+}: \operatorname{deg}(\bar{v}) \leq t\right\}, \quad \bar{U}_{t}=\bar{V}_{t} \cap \bar{U}^{+}, \\
\bar{\varphi}_{t}: \mathbb{P}\left(\bar{P}_{t}\right) \rightarrow \mathbb{P}\left(\bar{U}_{t+\operatorname{deg}\left(u_{0}\right)}\right), \quad[\bar{q}] \mapsto\left[\bar{u}_{0} \bar{q}\right], \\
\bar{\gamma}_{s}: \mathbb{P}\left(\bar{V}_{s}\right) \times \mathbb{P}\left(\bar{P}_{\operatorname{deg}\left(u_{0}\right)-s}\right) \rightarrow \mathbb{P}\left(\bar{V}_{\operatorname{deg}\left(u_{0}\right)}\right), \quad([\bar{v}],[\bar{q}]) \rightarrow[\bar{v} \bar{q}] .
\end{gathered}
$$

By base change, $\operatorname{Im}\left(\bar{\varphi}_{t}\right)$ is the zero set of the polynomials $\left\{\bar{g}: g \in G_{t}\right\}$. Similarly, $\operatorname{Im}\left(\bar{\gamma}_{s}\right)$ is the zero set of the polynomials $\bar{h}, h \in H_{s}$. From $\bar{u}_{0}=\bar{c} \cdot \bar{a}$ we obtain $\operatorname{deg}\left(\bar{u}_{0}\right)=\operatorname{deg}(\bar{c})+\operatorname{deg}(\bar{a})$. Assuming $\operatorname{deg}(\bar{a})>0$, it follows that $\bar{u}_{0} \in \operatorname{Im}\left(\bar{\gamma}_{s}\right)$ for $0 \leq s=\operatorname{deg}(\bar{c})<\operatorname{deg}\left(\bar{u}_{0}\right)=\operatorname{deg}\left(u_{0}\right)$. Hence $\bar{h}\left(\bar{u}_{0}\right)=\overline{h\left(u_{0}\right)}=0$ for all polynomials $h \in H_{s}$. But this contradicts (7.4.1): $\bar{h}_{s}\left(u_{0}\right) \neq 0$ by construction of $R$ and $\mathfrak{m}$. Hence $\operatorname{deg}(\bar{a})=0$, proving that $\bar{u}_{0}$ is also a generator of $\bar{U}_{\mathcal{A}}^{+}: \bar{U}_{\mathcal{A}}^{+}=\bar{u}_{0} \overline{\mathcal{A}}^{+}$.

Recall the element $v_{0} \in U^{+} \backslash u_{0} Q^{+}$. We have $0 \neq \bar{v}_{0} \in \bar{U}_{\mathcal{A}}^{+}=\bar{u}_{0} \overline{\mathcal{A}}^{+}$. Hence $\bar{g}\left(\bar{v}_{0}\right)=\overline{g\left(v_{0}\right)}=0$ for all $g \in G_{d}$. But this contradicts (7.4.2): $\overline{g_{d}\left(v_{0}\right)} \neq 0$ by construction of $R$ and $\mathfrak{m}$. Thus, we have arrived at the final contradiction: There does not exist $v_{0} \in U^{+} \backslash u_{0} Q^{+}$. It follows that $U$ is indeed generated by $u_{0}$.

[^1]:    ${ }^{2}$ As we have mentioned already, a distinguished "Cartan subalgebra" is part of the definition of a Lie torus.

[^2]:    ${ }^{3}$ It will not be sufficient in the following to consider only algebras over fields.
    ${ }^{4}$ We use $\mathcal{A}_{(\mathcal{C})}$ instead of $\mathcal{A}_{\mathcal{C}}$ since the latter usually denotes base change.
