Predicting the potential impact of a cytotoxic T-lymphocyte HIV vaccine: How often should you vaccinate and how strong should the vaccine be?

Robert Smith?

The University of Ottawa

HIV vaccines

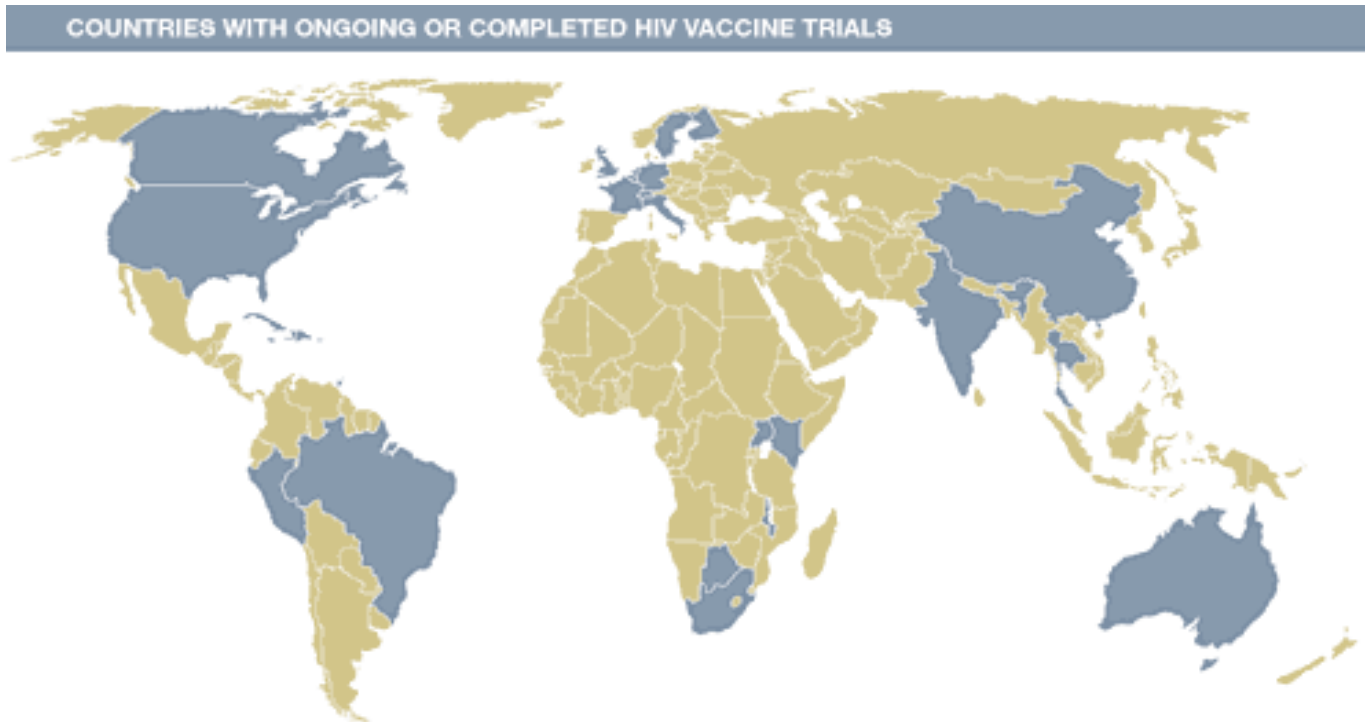
- HIV now infects 33 million adults worldwide

HIV vaccines

- HIV now infects 33 million adults worldwide
- An HIV vaccine represents the best hope of controlling the disease

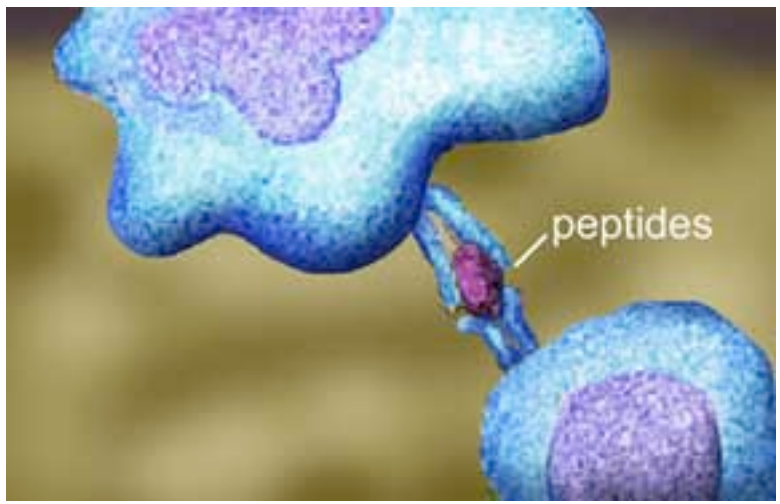
HIV vaccines

- HIV now infects 33 million adults worldwide
- An HIV vaccine represents the best hope of controlling the disease
- $682 million is spent on HIV vaccine research annually.



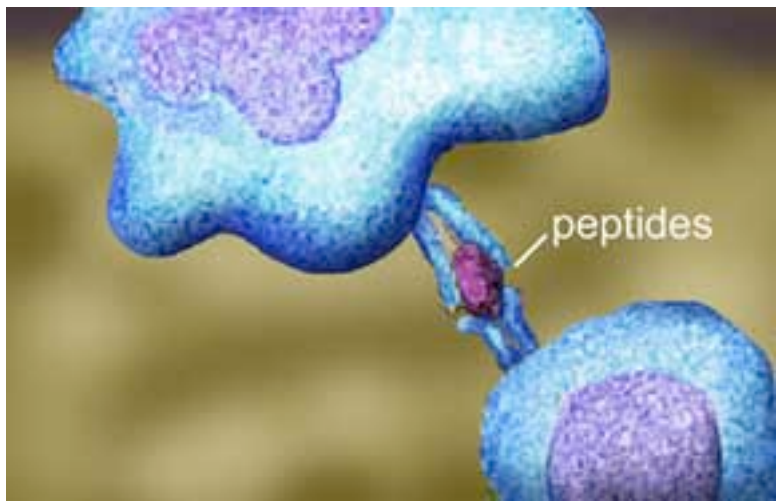
Cytotoxic T Lymphocytes (CTLs)

- Cells with the ability to identify and destroy virally infected cells in the body



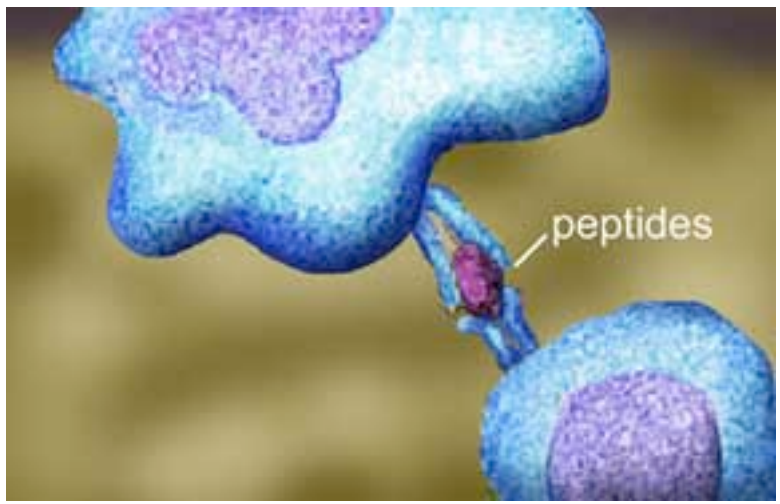
Cytotoxic T Lymphocytes (CTLs)

- Cells with the ability to identify and destroy virally infected cells in the body
- Activated via specific recognition of viral fragments



Cytotoxic T Lymphocytes (CTLs)

- Cells with the ability to identify and destroy virally infected cells in the body
- Activated via specific recognition of viral fragments
- One of the body's best natural defence mechanisms.



CTL vaccines

- If CTLs can be boosted at regular intervals, they can attack infected T-helper cells

CTL vaccines

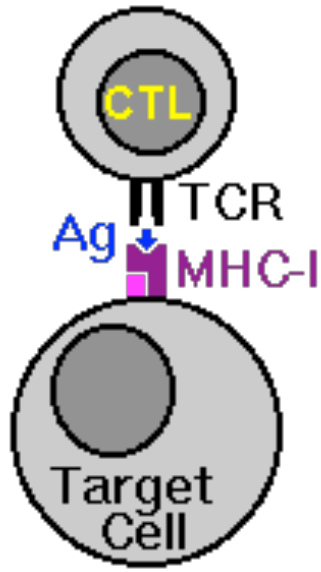
- If CTLs can be boosted at regular intervals, they can attack infected T-helper cells
- A vaccine that stimulates the CTL response has been described as the best hope for control of HIV

CTL vaccines

- If CTLs can be boosted at regular intervals, they can attack infected T-helper cells
- A vaccine that stimulates the CTL response has been described as the best hope for control of HIV
- Such a post-infection “vaccine” would be administered regularly and indefinitely.

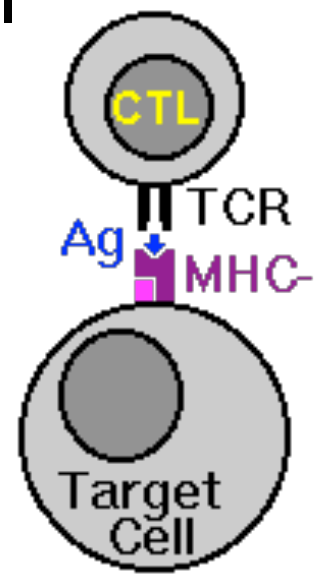
Infected $CD4^+$ T cells

- Die at death rate *d*



Infected $CD4^+$ T cells

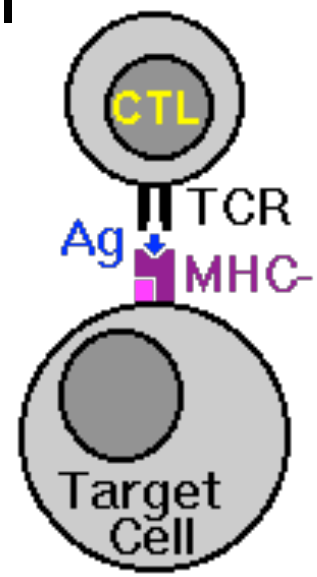
- Die at death rate *d*
- Cleared by CTLs at rate *p*, proportional to the density of both types



Infected $CD4^+$ T cells

- Die at death rate *d*
- Cleared by CTLs at rate *p*, proportional to the density of both types

Key approximation:

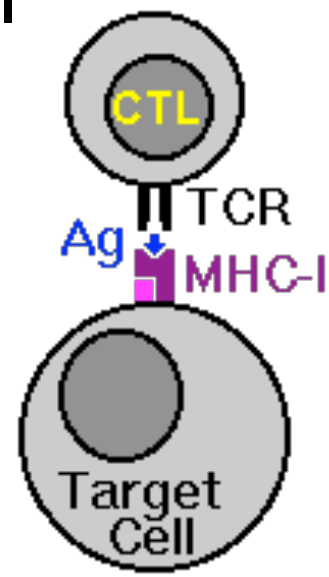


Infected $CD4^+$ T cells

- Die at death rate *d*
- Cleared by CTLs at rate *p*, proportional to the density of both types

Key approximation:

- We assume the production rate of infected cells is constant, π



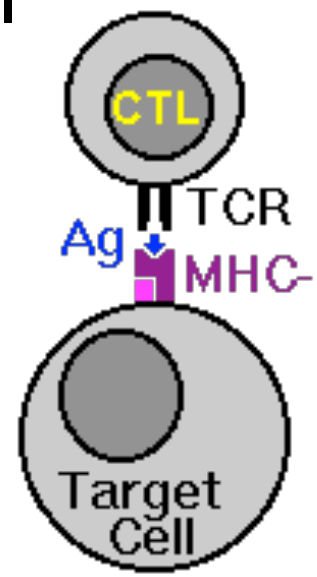
Infected $CD4^+$ T cells

- Die at death rate *d*
- Cleared by CTLs at rate *p*, proportional to the density of both types

Key approximation:

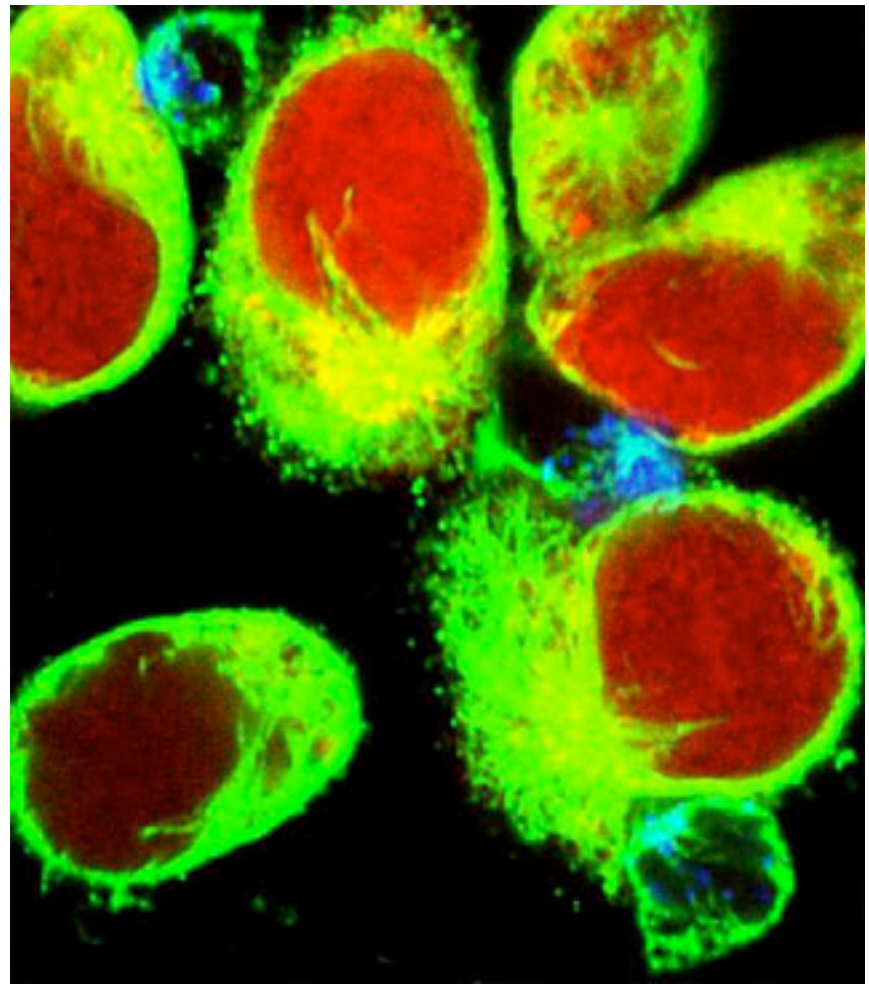
- We assume the production rate of infected cells is constant, π

  (thus we use a steady-state viral load approximation when estimating parameters).



CTLs

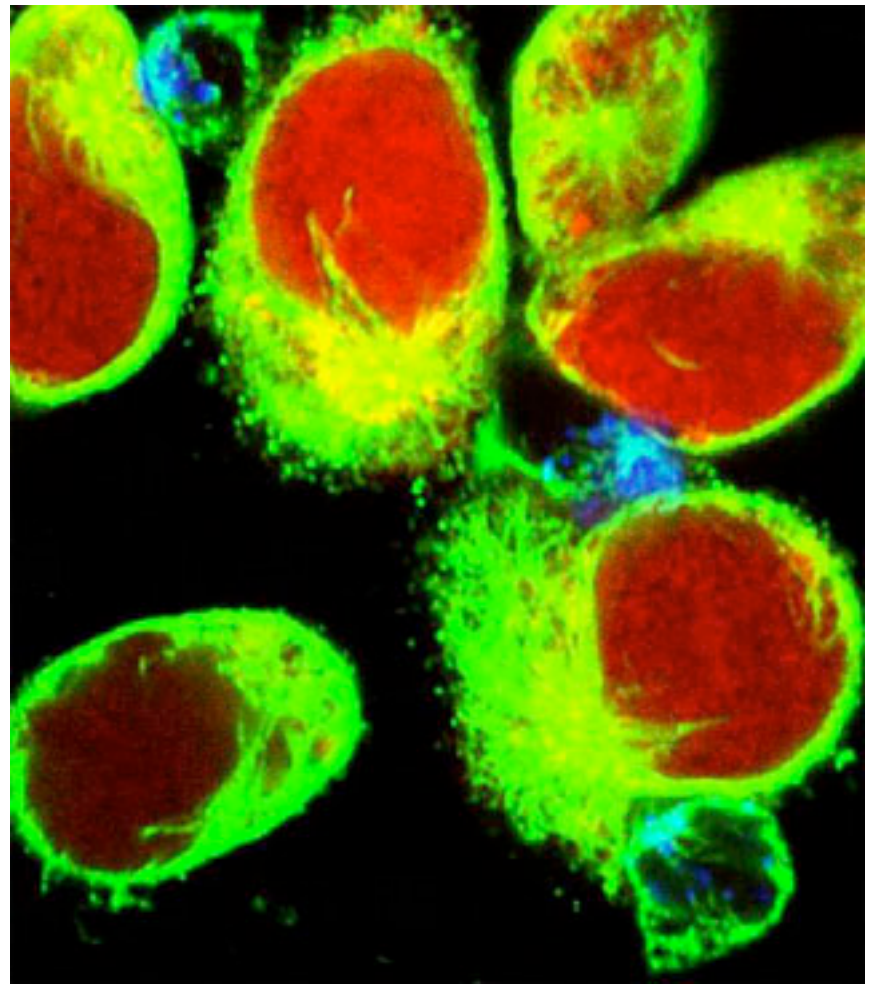
- Proliferate at rate α, proportional to density of both CTLs and infected T cells



Three CTLs (blue) annihilate target cells (red)

CTLs

- Proliferate at rate α, proportional to density of both CTLs and infected T cells
- Die at death rate δ.



Three CTLs (blue) annihilate target cells (red)

The model without vaccination

- Thus the model (without vaccination) is

The model without vaccination

- Thus the model (without vaccination) is

$$\frac{dT}{dt} = \pi - dT - pCT$$
$$\frac{dC}{dt} = \alpha CT - \delta C\,.$$

T=infected T cells π*=production rate* d,δ*=death rates*
C=CTLs α*=proliferation rate* *p=clearance rate*

Steady states

Two steady states:

Steady states

Two steady states:

- trivial
  (no CTLs)

$$(\hat{T}, \hat{C}) = \left(\frac{\pi}{d}, 0\right)$$

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Steady states

Two steady states:

- trivial
  (no CTLs)

$$(\hat{T}, \hat{C}) = \left(\frac{\pi}{d}, 0\right)$$

- nontrivial
  (coexistence)

$$(\bar{T}, \bar{C}) = \left(\frac{\delta}{\alpha}, \frac{\alpha\pi - \delta d}{p\delta}\right).$$

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

- For the trivial steady state, the Jacobian is

T=infected T cells π*=production rate* d,δ*=death rates*
C=CTLs α*=proliferation rate* *p=clearance rate*

Stability

- For the trivial steady state, the Jacobian is

$$J|_{(\hat{T},\hat{C})} = \begin{bmatrix} -d & -\frac{p\pi}{d} \\ 0 & \frac{\alpha\pi}{d} - \delta \end{bmatrix}$$

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

- For the trivial steady state, the Jacobian is

$$J|_{(\hat{T},\hat{C})} = \begin{bmatrix} -d & -\frac{p\pi}{d} \\ 0 & \frac{\alpha\pi}{d} - \delta \end{bmatrix}$$

Thus unstable iff $\bar{C} = (\alpha\pi - \delta d)/p\delta > 0$

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

- For the trivial steady state, the Jacobian is

$$J|_{(\hat{T},\hat{C})} = \begin{bmatrix} -d & -\frac{p\pi}{d} \\ 0 & \frac{\alpha\pi}{d} - \delta \end{bmatrix}$$

  Thus unstable iff $\bar{C} = (\alpha\pi - \delta d)/p\delta > 0$

- For the nontrivial steady state, the characteristic polynomial is

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

- For the trivial steady state, the Jacobian is

$$J|_{(\hat{T},\hat{C})} = \begin{bmatrix} -d & -\frac{p\pi}{d} \\ 0 & \frac{\alpha\pi}{d} - \delta \end{bmatrix}$$

  Thus unstable iff $\bar{C} = (\alpha\pi - \delta d)/p\delta > 0$

- For the nontrivial steady state, the characteristic polynomial is

$$\det(J|_{(\bar{T},\bar{C})} - \lambda I) = \lambda^2 + (d + p\bar{C})\lambda + p\delta\bar{C}/\alpha$$

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

- For the trivial steady state, the Jacobian is

$$J|_{(\hat{T},\hat{C})} = \begin{bmatrix} -d & -\frac{p\pi}{d} \\ 0 & \frac{\alpha\pi}{d} - \delta \end{bmatrix}$$

  Thus unstable iff $\bar{C} = (\alpha\pi - \delta d)/p\delta > 0$

- For the nontrivial steady state, the characteristic polynomial is

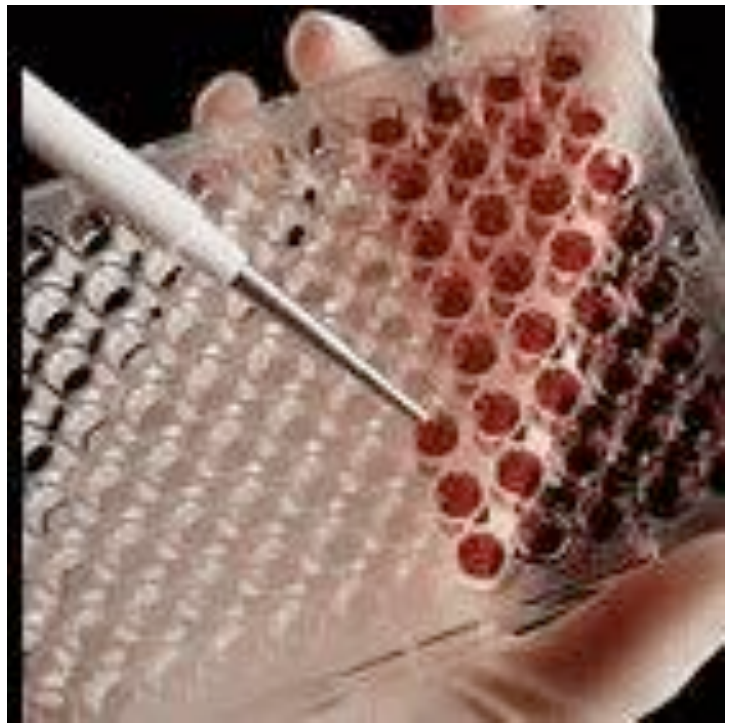
$$\det(J|_{(\bar{T},\bar{C})} - \lambda I) = \lambda^2 + (d + p\bar{C})\lambda + p\delta\bar{C}/\alpha$$

  Thus stable whenever $\bar{C} > 0$.

T=infected T cells π=production rate d,δ=death rates
C=CTLs α=proliferation rate p=clearance rate

Stability

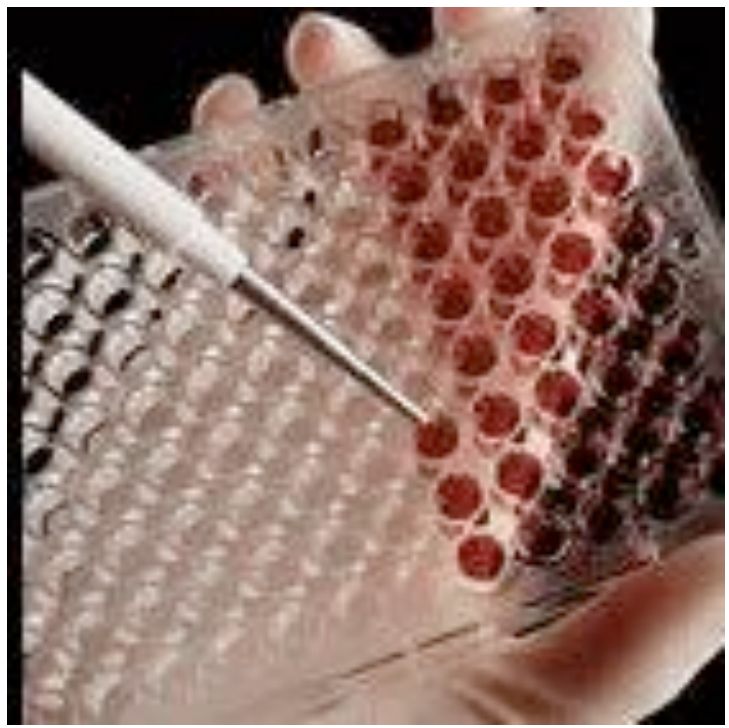
Hence:



Stability

Hence:

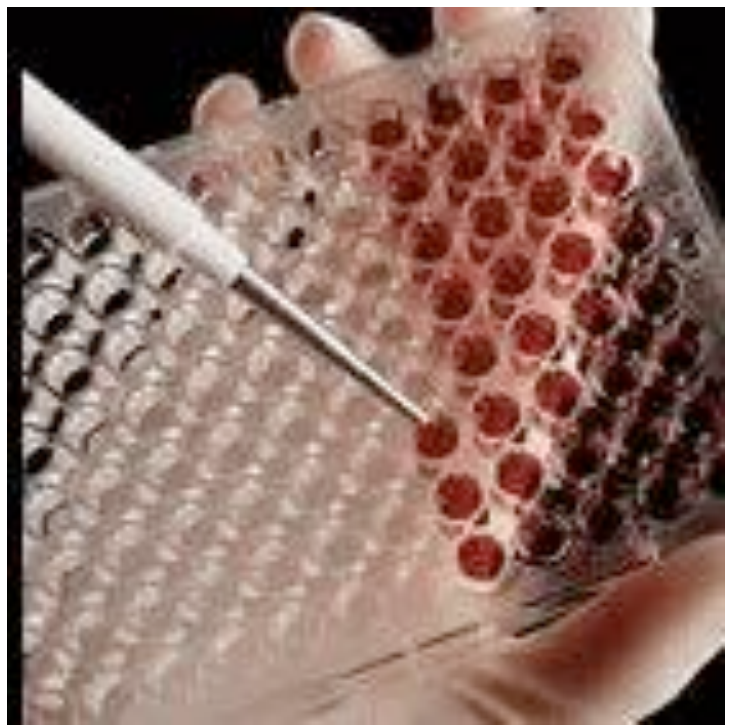
- the trivial steady state is unstable iff the nontrivial steady state exists in the positive plane



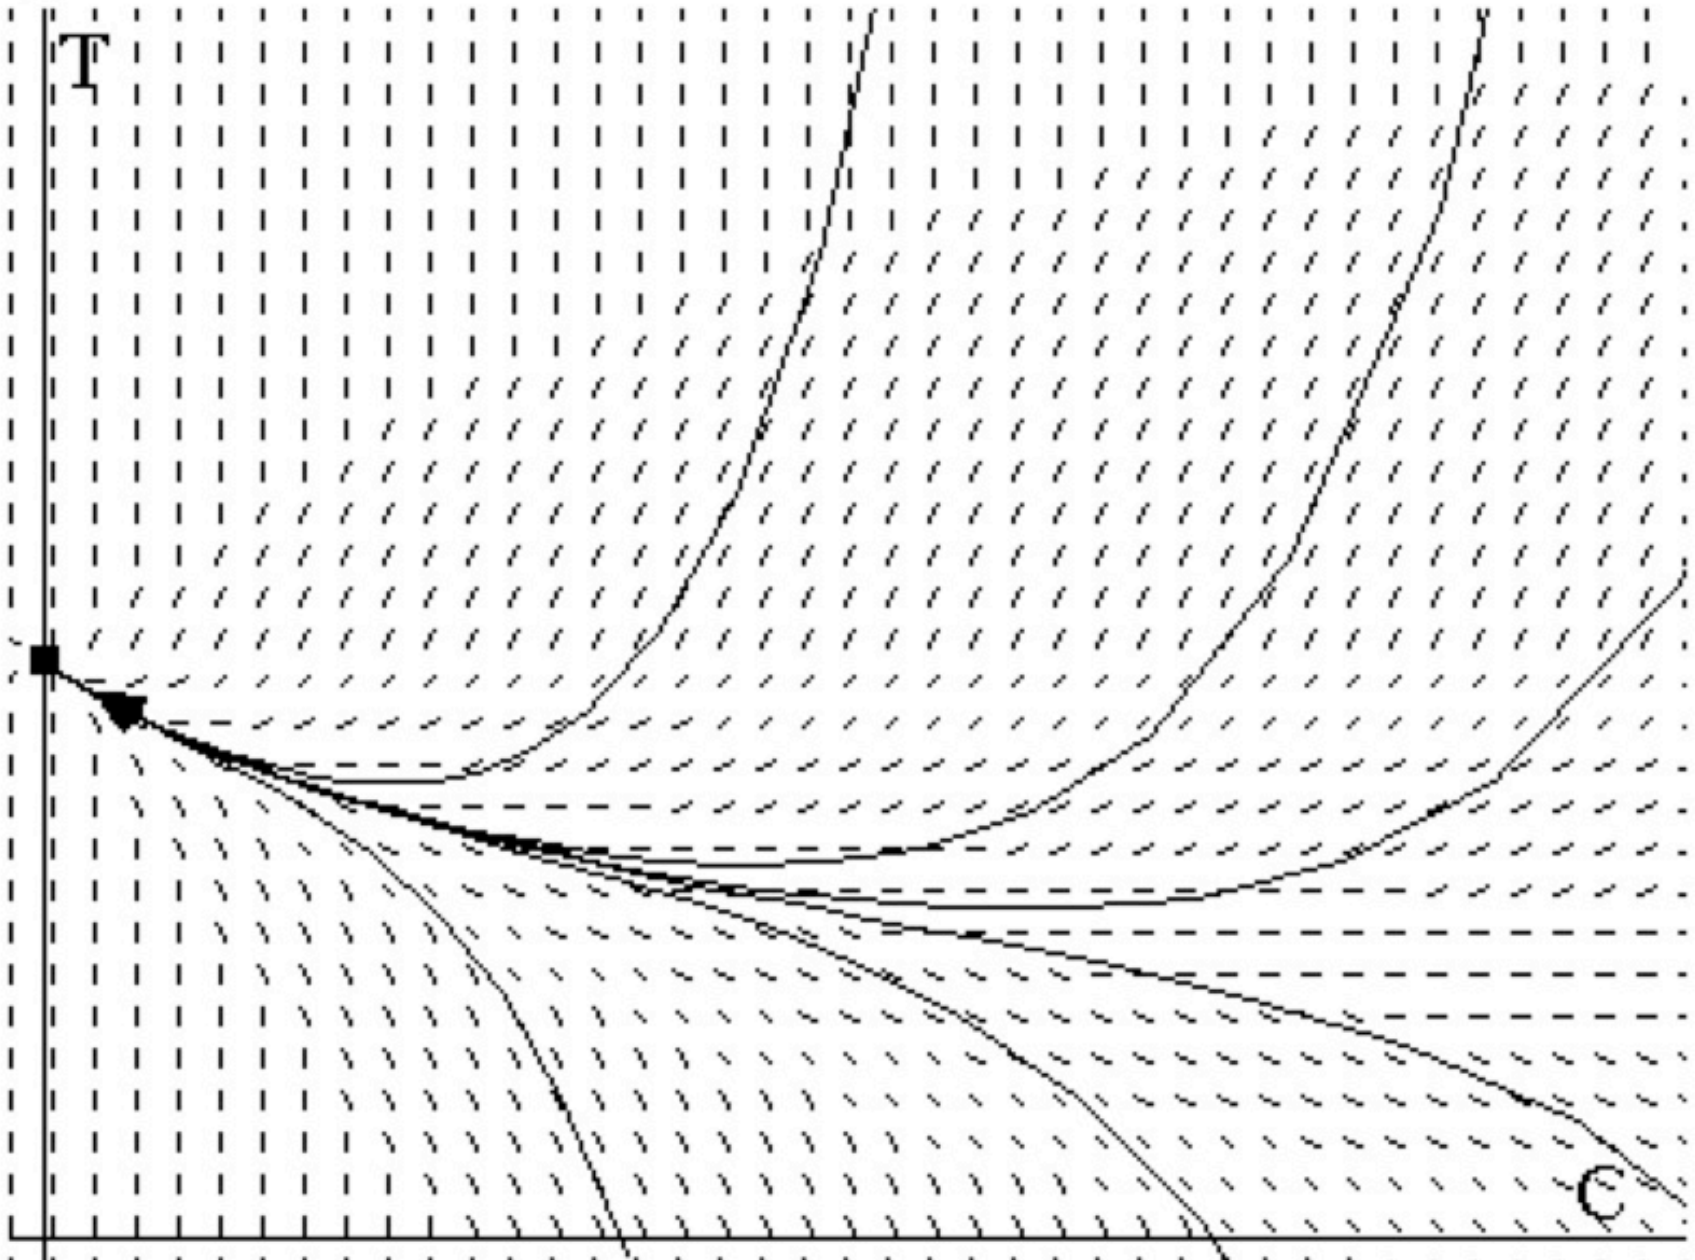
Stability

Hence:

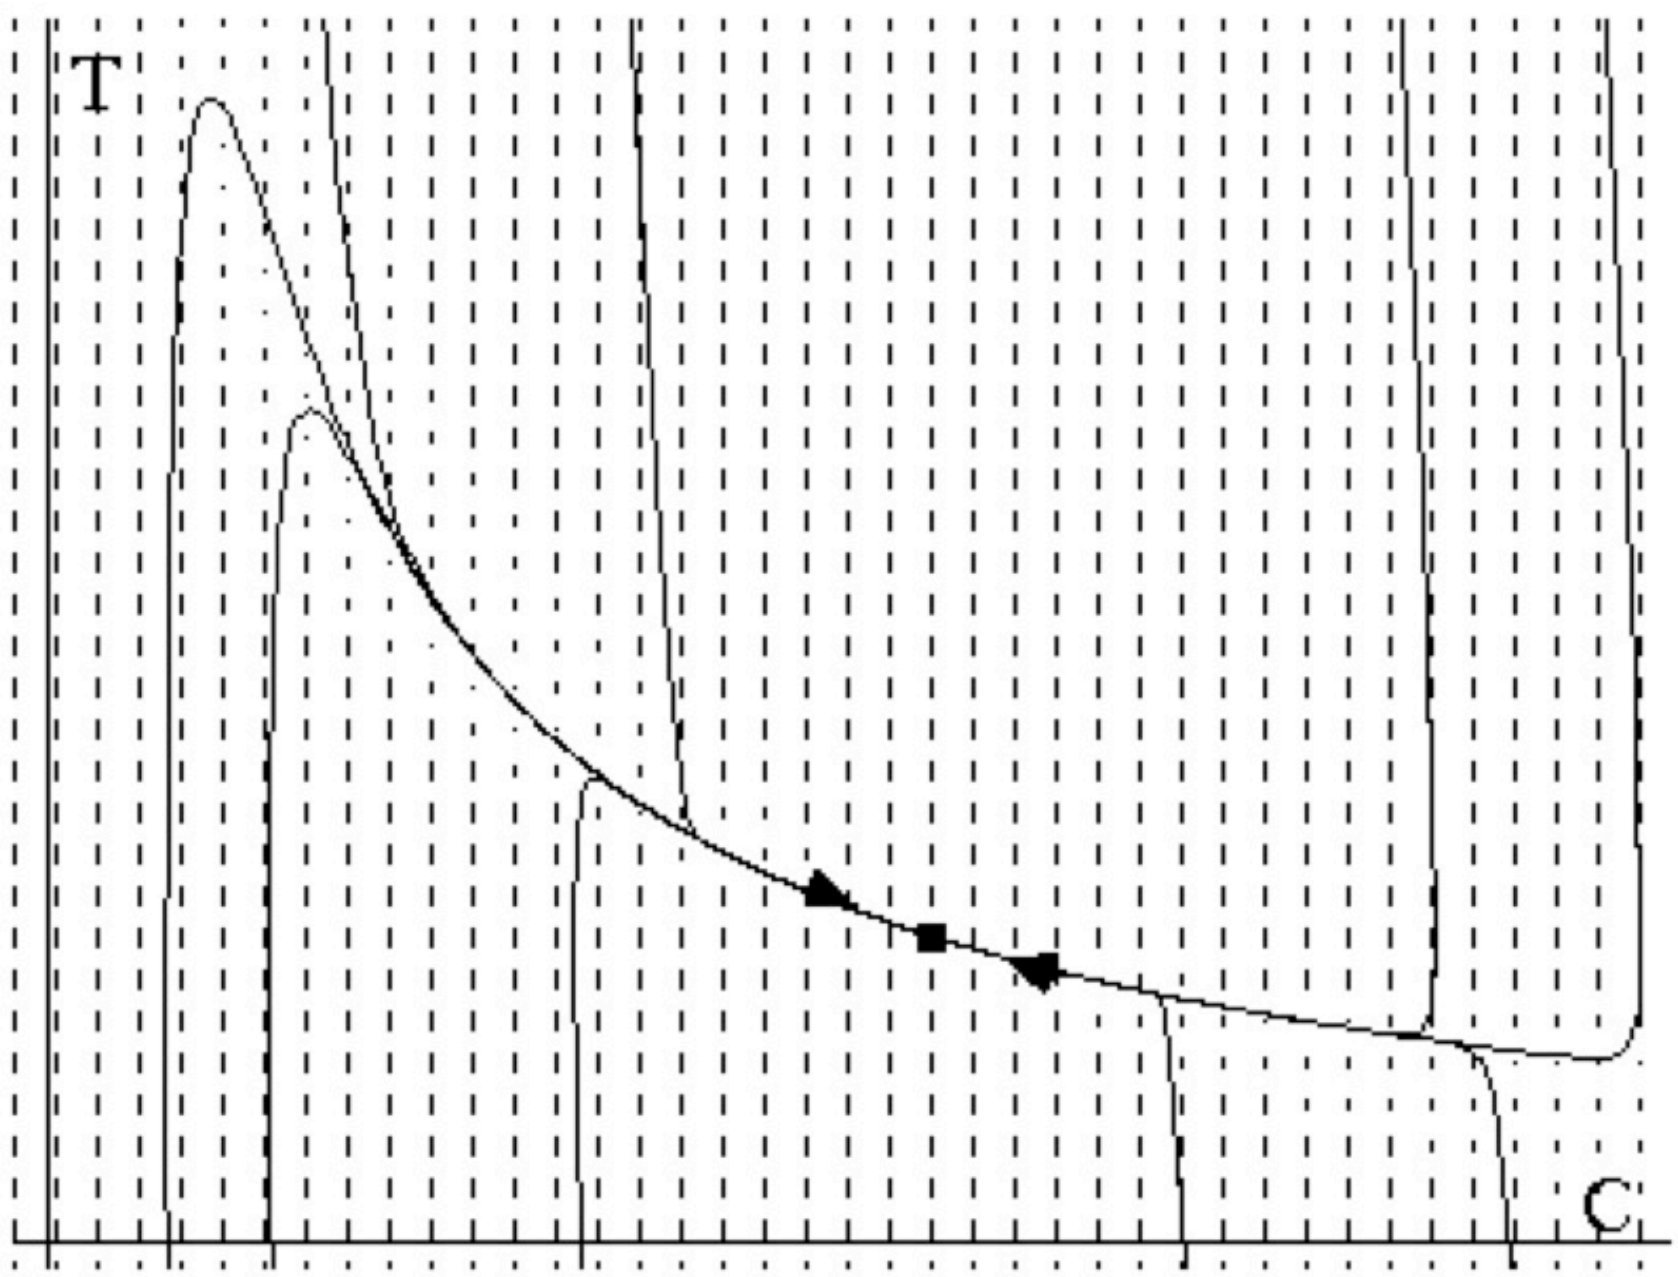
- the trivial steady state is unstable iff the nontrivial steady state exists in the positive plane
- the nontrivial steady state is asymptotically stable whenever it exists in the positive plane.



Nontrivial eq^{m} absent $\Leftrightarrow$ trivial eq^{m} stable



Nontrivial eq^{m} stable in the positive plane



Vaccination

- A fixed boost of CTLs, C^i

Vaccination

- A fixed boost of CTLs, C^i
- Given at regular times, t_k

Vaccination

- A fixed boost of CTLs, C^i
- Given at regular times, t_k
- We assume the vaccine effect is instantaneous...

Vaccination

- A fixed boost of CTLs, C^i
- Given at regular times, t_k
- We assume the vaccine effect is instantaneous...

  ...this results in a series of *impulsive differential equations*.

Impulsive effect

- According to impulsive theory, we can describe the nature of the impulse at time r_k via the difference equation

Impulsive effect

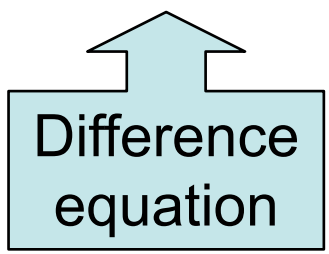
- According to impulsive theory, we can describe the nature of the impulse at time r_k via the difference equation

$$\Delta y \equiv y(r_k^+) - y(r_k^-) = f(r_k, y(r_k^-))$$

Impulsive effect

- According to impulsive theory, we can describe the nature of the impulse at time r_k via the difference equation

$$\Delta y \equiv y(r_k^+) - y(r_k^-) = f(r_k, y(r_k^-))$$



Impulsive effect

- According to impulsive theory, we can describe the nature of the impulse at time r_k via the difference equation

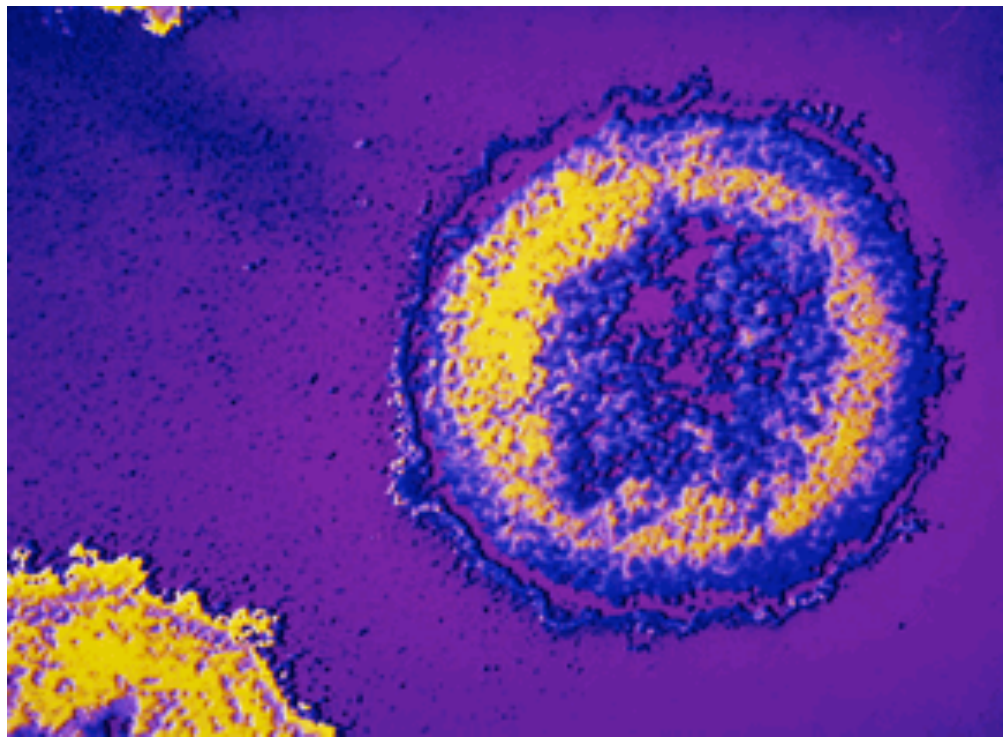
$$\Delta y \equiv y(r_k^+) - y(r_k^-) = f(r_k, y(r_k^-))$$

Difference equation

Depends on the time of impulse and the state immediately beforehand.

Impulsive DEs

- Solutions are continuous for $t \neq r_k$

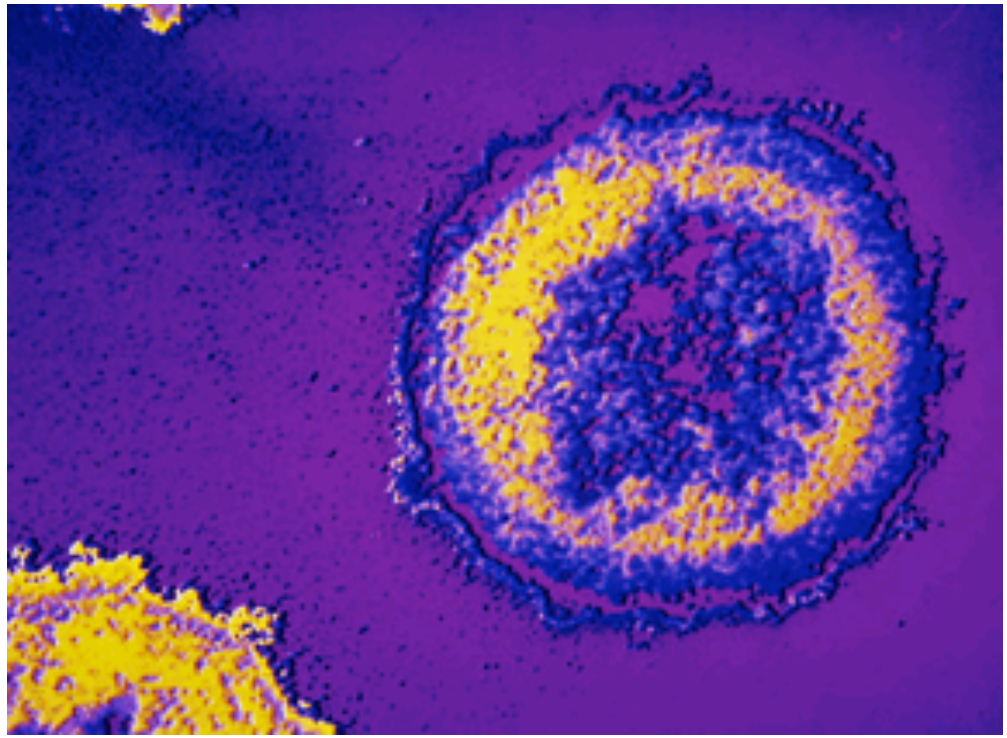


Thousands of HIV particles emerging from an infected T-cell

r_k=*impulse time*

Impulsive DEs

- Solutions are continuous for $t \neq r_k$
- Solutions undergo an instantaneous change in state when $t = r_k$.



Thousands of HIV particles emerging from an infected T-cell

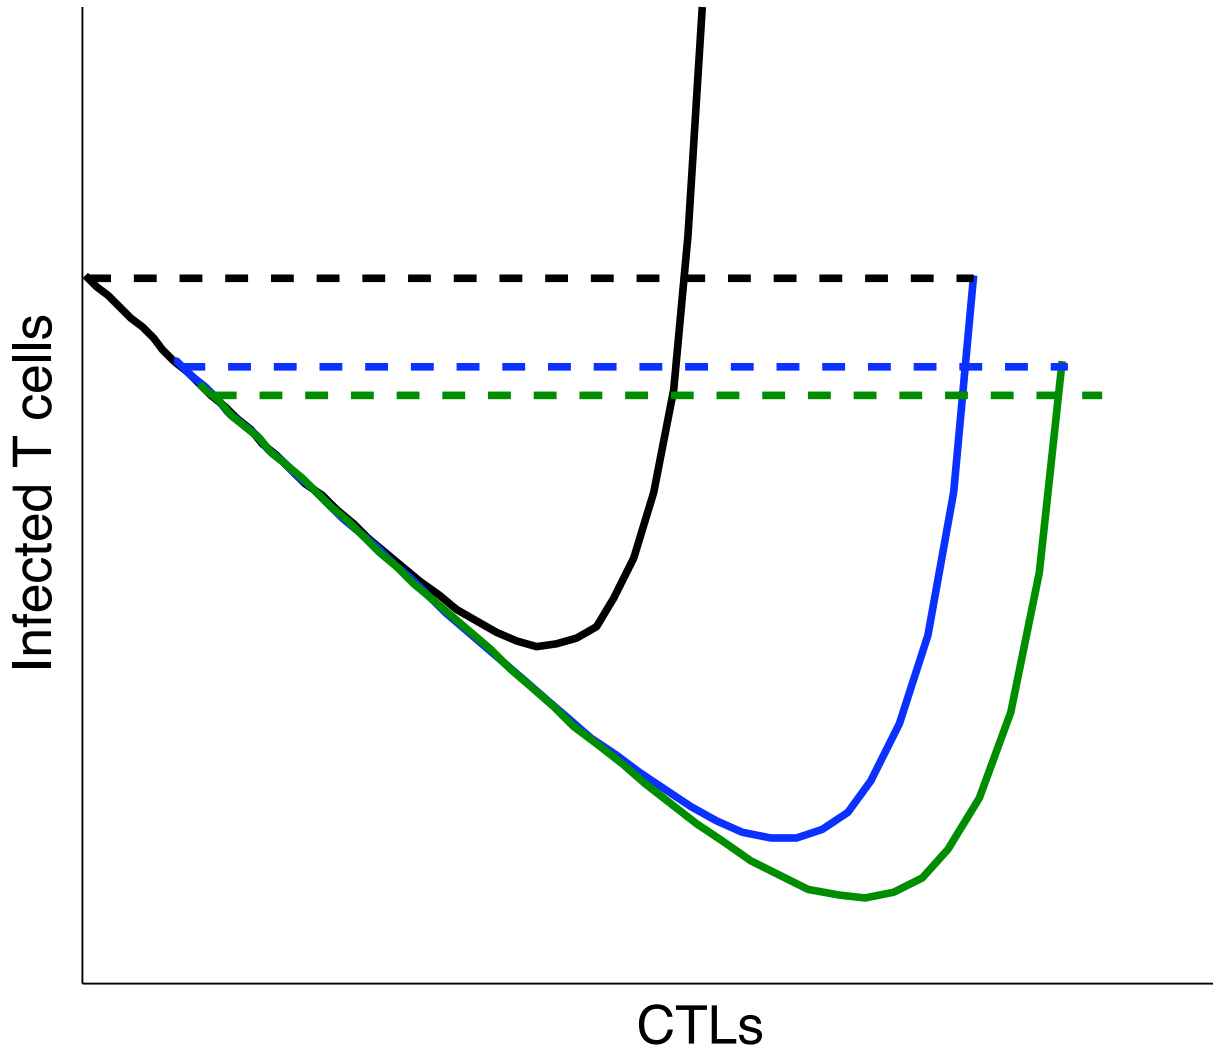
r_k=*impulse time*

Putting it together

- The model thus consists of a system of ODEs (infected T cells and CTLs) together with a difference equation (CTL boost).

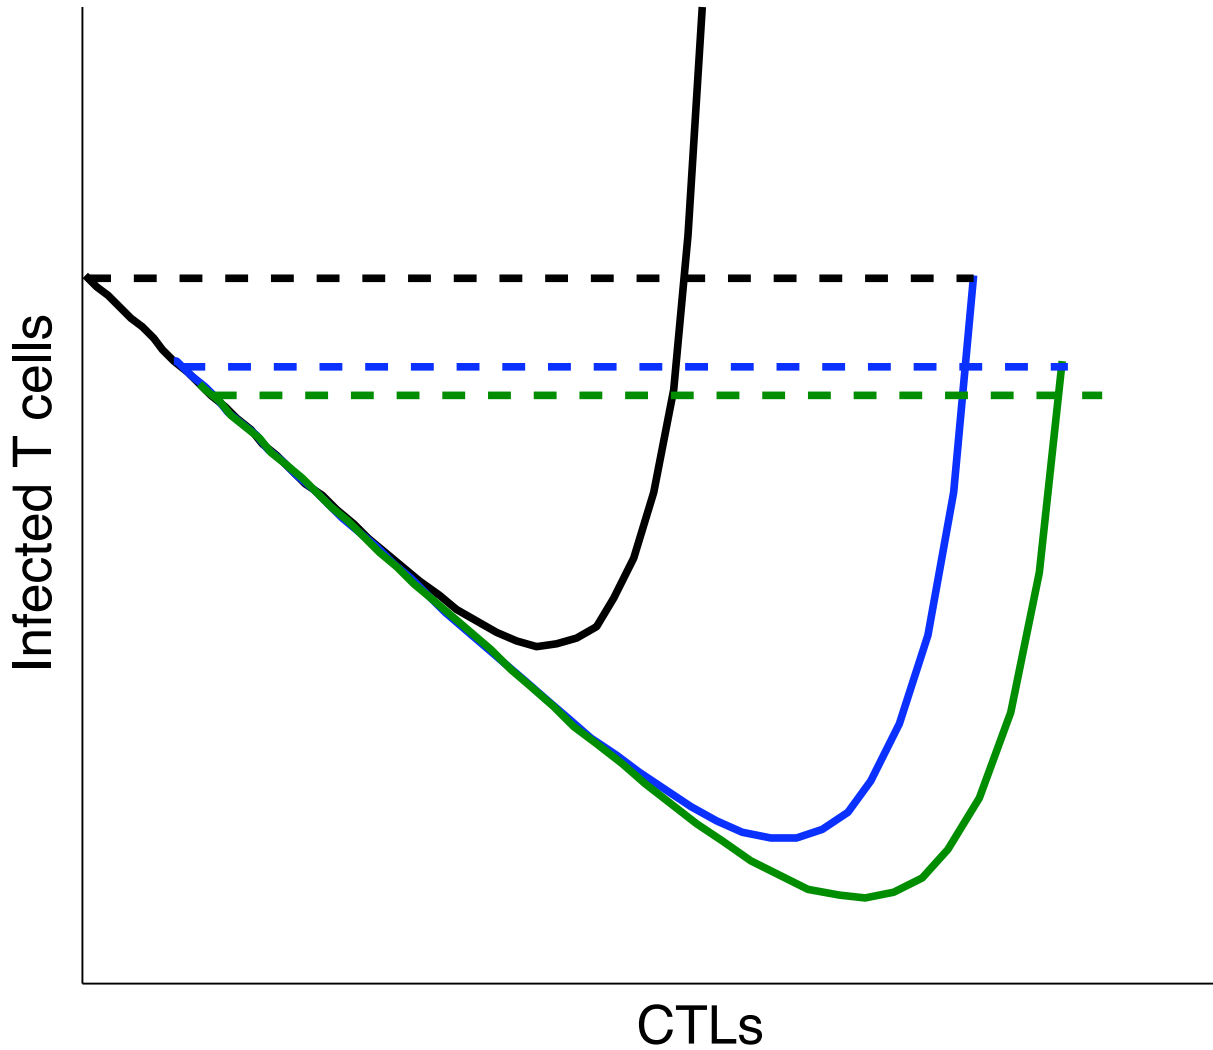
Impulsive interruption

- The impulsive effect “interrupts” the continuous trajectories



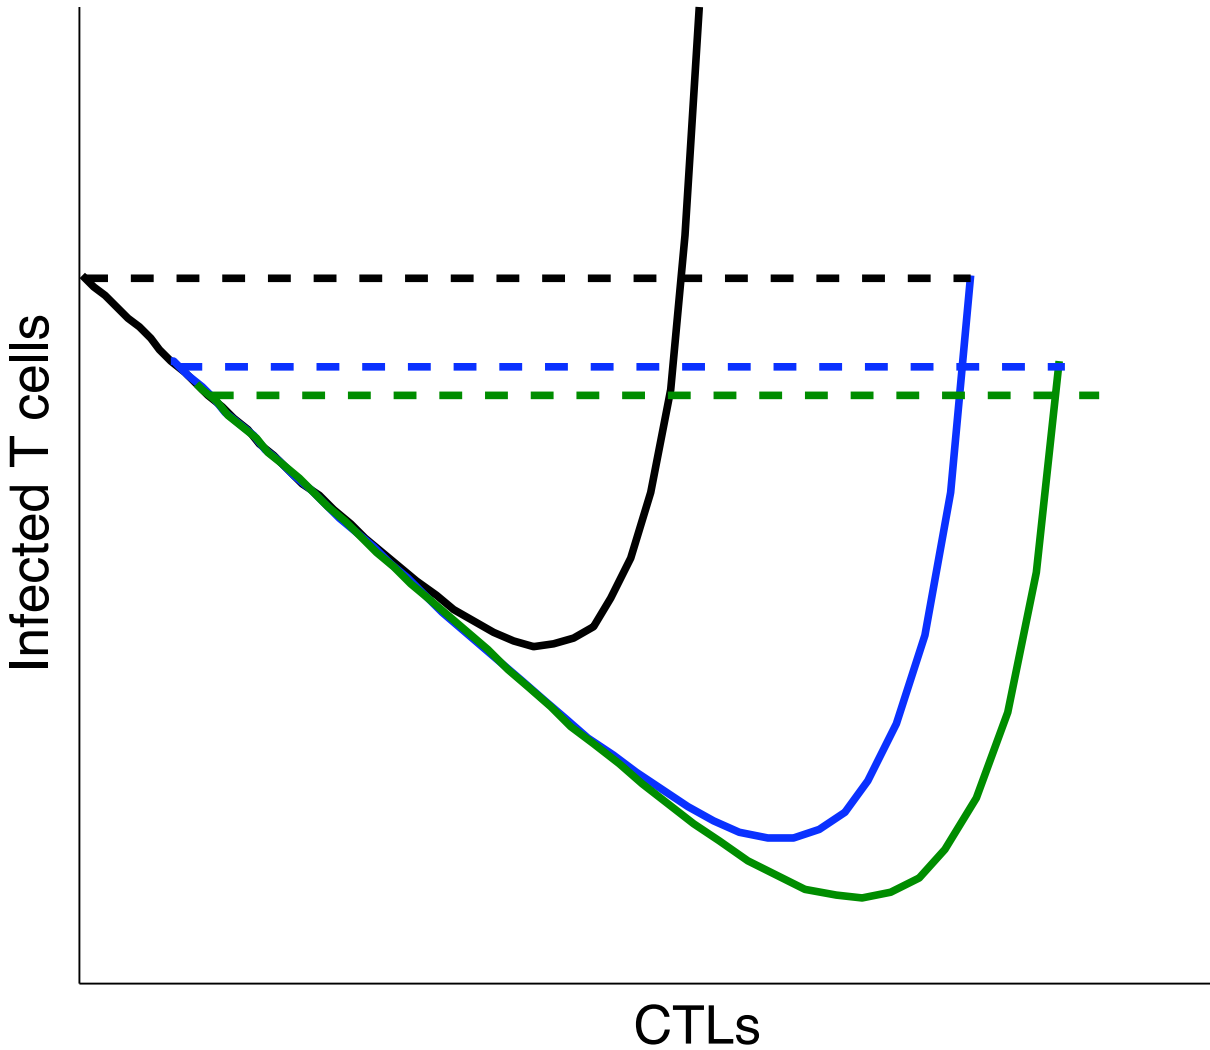
Impulsive interruption

- The impulsive effect “interrupts” the continuous trajectories
- The cycle is restarted



Impulsive interruption

- The impulsive effect “interrupts” the continuous trajectories
- The cycle is restarted
- It continues until the next “interruption”.



The model (with vaccination)

- Thus, the impulsive model is

The model (with vaccination)

- Thus, the impulsive model is

$$\begin{aligned}
\frac{dT}{dt} &= \pi - dT - pCT && t \neq t_k \\
\frac{dC}{dt} &= \alpha CT - \delta C && t \neq t_k \\
\Delta C &= C^i && t = t_k\,.
\end{aligned}$$

T=infected T cells π*=production rate* d,δ*=death rates* C^i*=vaccine strength*
C=CTLs α*=proliferation rate* *p=clearance rate* t_k*=vaccination time*

Implicit solution within a cycle

- Since

$$C' \quad = \quad C(\alpha T - \delta)$$

T=infected cells C=CTLs
α=proliferation rate δ=death rate

Implicit solution within a cycle

- Since

$$C' = C(\alpha T - \delta)$$

$$\int_0^t \frac{dC}{C} = \int_0^t (\alpha T(u) - \delta) du$$

T=infected cells C=CTLs
α=proliferation rate δ=death rate

Implicit solution within a cycle

- Since

$$C' = C(\alpha T - \delta)$$

$$\int_0^t \frac{dC}{C} = \int_0^t (\alpha T(u) - \delta) du$$

$$\therefore \quad C(t) = C(0) e^{\int_0^t (\alpha T(u) - \delta) du}.$$

T=infected cells C=CTLs
α=proliferation rate δ=death rate

Defining T_{int}

- Define

  where $\tau = t_{k+1} - t_k$ is the vaccine administration interval (assumed constant)
- T_{int} is a measure of the ratio of the number of CTLs at the end of an impulsive cycle to those at the beginning

T=infected T cells α*=proliferation rate*
δ*=death rate* t_k*=vaccination time*

Defining T_{int}

- Define

$$T_{\text{int}} = e^{\int_0^{\tau}(\alpha T(u)-\delta)du}$$

where $\tau = t_{k+1} - t_k$ is the vaccine administration interval (assumed constant)

- T_{int} is a measure of the ratio of the number of CTLs at the end of an impulsive cycle to those at the beginning

T=infected T cells α*=proliferation rate* δ*=death rate* t_k*=vaccination time*

Defining T_{int}

- Define

$$T_{\text{int}} = e^{\int_0^{\tau}(\alpha T(u)-\delta)du}$$

  where $\tau = t_{k+1} - t_k$ is the vaccine administration interval (assumed constant)
- T_{int} is a measure of the ratio of the number of CTLs at the end of an impulsive cycle to those at the beginning
- Thus, $T_{\text{int}}<1$ is necessary for an impulsive orbit to exist.

T=infected T cells α=proliferation rate
δ=death rate t_k=vaccination time

An impulsive periodic orbit

- In particular, if $C(0^+) = \frac{C^i}{1-T_{\text{int}}}$

T_{int}=cell ratio measure C=CTLs
C^i=vaccine strength τ=vaccination period

An impulsive periodic orbit

- In particular, if $C(0^+) = \frac{C^i}{1-T_{\text{int}}}$

$$C(\tau^-) = \frac{C^i T_{\text{int}}}{1 - T_{\text{int}}}$$

T_{int}=cell ratio measure C=CTLs
C^i=vaccine strength τ=vaccination period

An impulsive periodic orbit

- In particular, if $C(0^+) = \frac{C^i}{1-T_{\text{int}}}$

$$C(\tau^-) = \frac{C^i T_{\text{int}}}{1-T_{\text{int}}}$$

$$C(\tau^+) = \frac{C^i T_{\text{int}}}{1-T_{\text{int}}} + C^i$$

T_{int}=cell ratio measure C=CTLs
C^i=vaccine strength τ=vaccination period

An impulsive periodic orbit

- In particular, if $C(0^+) = \frac{C^i}{1-T_{\text{int}}}$

$$
\begin{aligned}
C(\tau^-) &= \frac{C^i T_{\text{int}}}{1-T_{\text{int}}} \\
C(\tau^+) &= \frac{C^i T_{\text{int}}}{1-T_{\text{int}}} + C^i \\
&= \frac{C^i}{1-T_{\text{int}}}
\end{aligned}
$$

T_{int}=cell ratio measure C=CTLs
C^i=vaccine strength τ=vaccination period

An impulsive periodic orbit

- In particular, if $C(0^+) = \frac{C^i}{1-T_{\text{int}}}$

$$
\begin{aligned}
C(\tau^-) &= \frac{C^i T_{\text{int}}}{1-T_{\text{int}}} \\
C(\tau^+) &= \frac{C^i T_{\text{int}}}{1-T_{\text{int}}} + C^i \\
&= \frac{C^i}{1-T_{\text{int}}} \\
&= C(0^+)\,.
\end{aligned}
$$

T_{int}=cell ratio measure C=CTLs
C^i=vaccine strength τ=vaccination period

The orbit, with endpoints

- Thus we have an impulsive periodic orbit

The orbit, with endpoints

- Thus we have an impulsive periodic orbit

$$C(t) = \frac{C^i e^{\int_0^t (\alpha T(u) - \delta) du}}{1 - T_{\text{int}}}$$

T_{int}=cell ratio measure C=CTLs C^i=vaccine strength
α=proliferation rate δ=death rate τ=vaccination period

The orbit, with endpoints

- Thus we have an impulsive periodic orbit

$$C(t) = \frac{C^i e^{\int_0^t (\alpha T(u) - \delta) du}}{1 - T_{\text{int}}}$$

for $0 < t < \tau$

T_{int}=cell ratio measure C=CTLs C^i=vaccine strength
α=proliferation rate δ=death rate τ=vaccination period

The orbit, with endpoints

- Thus we have an impulsive periodic orbit

$$C(t) = \frac{C^i e^{\int_0^t (\alpha T(u) - \delta) du}}{1 - T_{\text{int}}}$$

  for $0 < t < \tau$

- Endpoints of the impulsive orbit are

T_{int}=cell ratio measure C=CTLs C^i=vaccine strength
α=proliferation rate δ=death rate τ=vaccination period

The orbit, with endpoints

- Thus we have an impulsive periodic orbit

$$C(t) = \frac{C^i e^{\int_0^t (\alpha T(u) - \delta) du}}{1 - T_{\text{int}}}$$

for $0 < t < \tau$

- Endpoints of the impulsive orbit are

$$C(0^+) = \frac{C^i}{1 - T_{\text{int}}} \quad \text{and} \quad C(\tau^-) = \frac{C^i T_{\text{int}}}{1 - T_{\text{int}}} .$$

Orbital asymptotic stability

- Hence, the nontrivial impulsive Floquet multiplier lies inside the unit circle

Orbital asymptotic stability

- Hence, the nontrivial impulsive Floquet multiplier lies inside the unit circle
- Thus, the impulsive periodic orbit is

Orbital asymptotic stability

- Hence, the nontrivial impulsive Floquet multiplier lies inside the unit circle
- Thus, the impulsive periodic orbit is

    a) orbitally asymptotically stable and

Orbital asymptotic stability

- Hence, the nontrivial impulsive Floquet multiplier lies inside the unit circle
- Thus, the impulsive periodic orbit is

  a) orbitally asymptotically stable and

  b) has the property of asymptotic phase.

A caveat

- Although this orbit exists and is stable it might not be unique

A caveat

- Although this orbit exists and is stable it might not be unique
- In particular, there might be impulsive orbits with more than one impulse per period

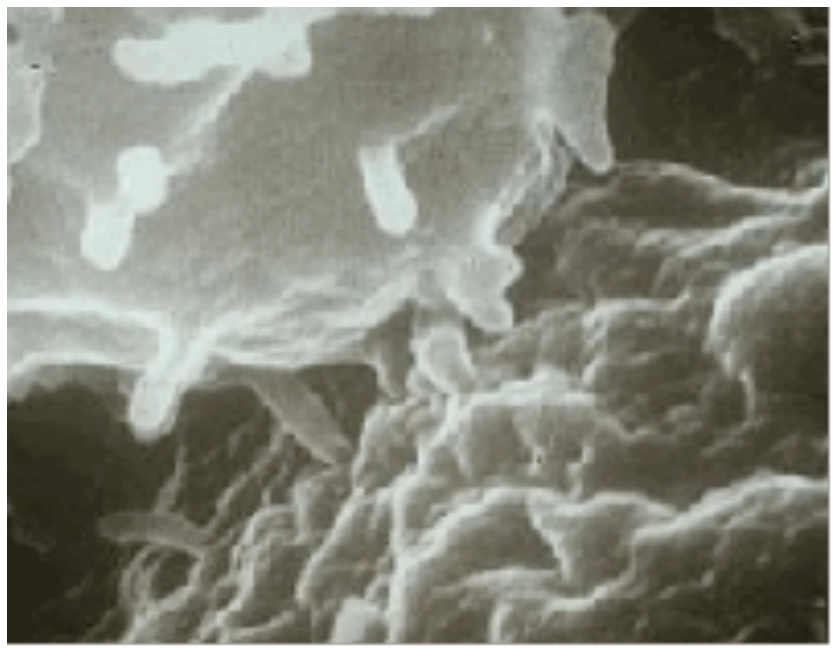
A caveat

- Although this orbit exists and is stable it might not be unique
- In particular, there might be impulsive orbits with more than one impulse per period
- However, this does not appear to be the case, for the parameter ranges under consideration.

Average # of infected T cells

- The average number of infected T cells during a single cycle of the impulsive periodic orbit is

$$T_{av} \equiv \frac{1}{\tau} \int_0^{\tau} T(u) du \,.$$

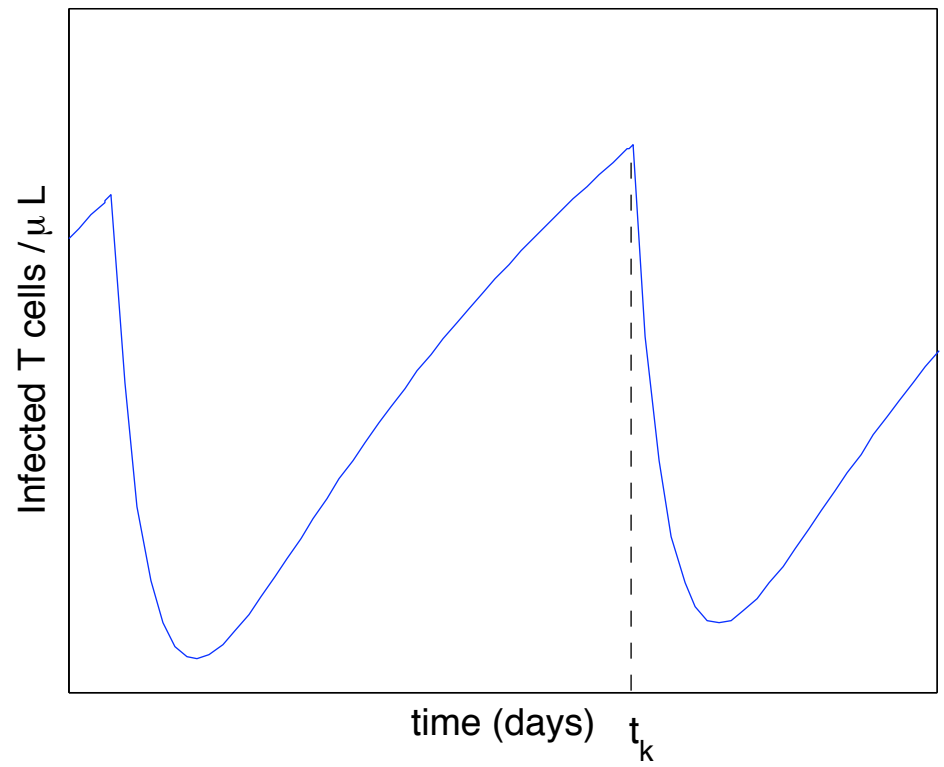


A CTL recognising a tumour

T=infected cells τ=vaccination period

Infected T cell minimum

- Easy to show:

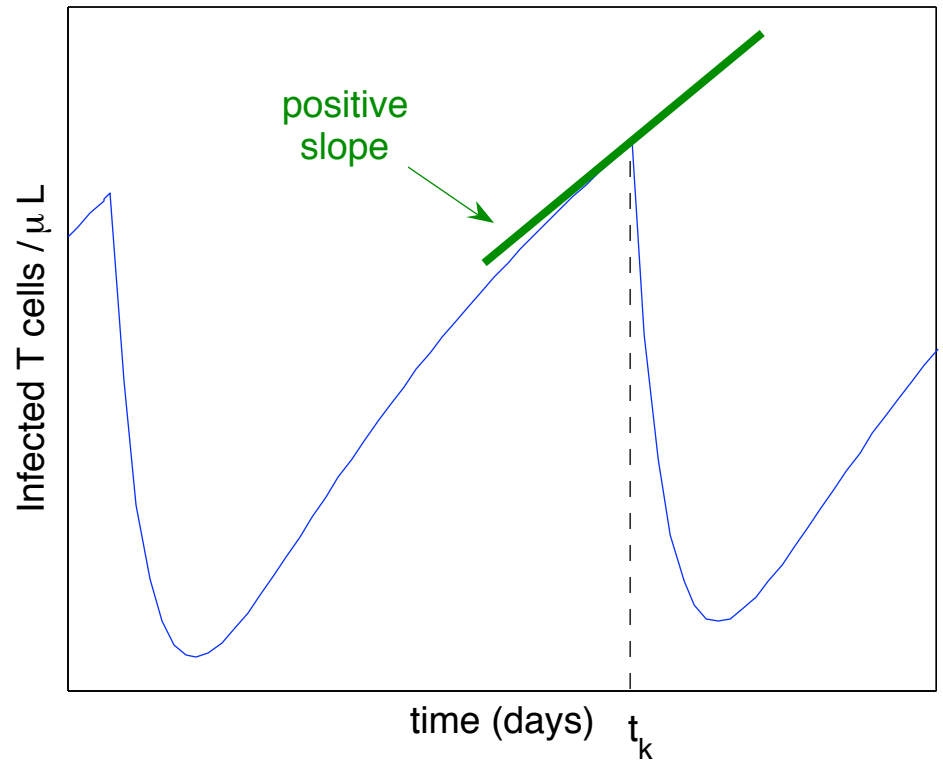


T=infected T cells C=CTLs t_k=vaccination time

Infected T cell minimum

- Easy to show:

$$\frac{dT}{dt}(t_k^+) < \frac{dT}{dt}(t_k^-)$$



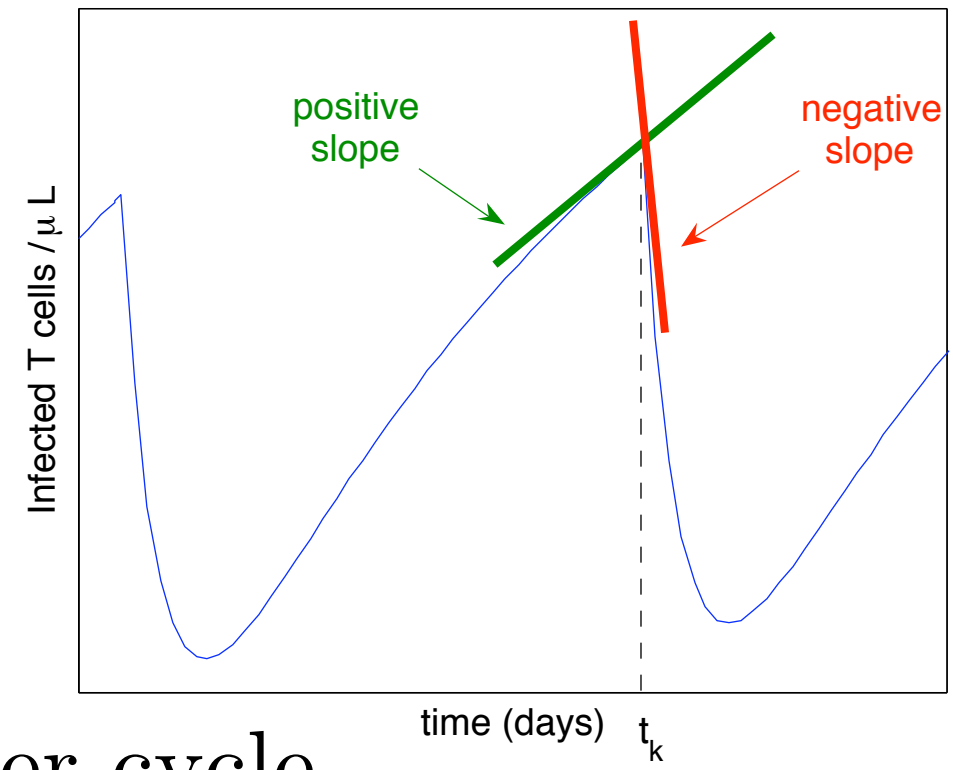
T=infected T cells C=CTLs t_k=vaccination time

Infected T cell minimum

- Easy to show:

$$\frac{dT}{dt}(t_k^+) < \frac{dT}{dt}(t_k^-)$$

$$\frac{dT}{dt} = 0 \quad \text{only once per cycle}$$



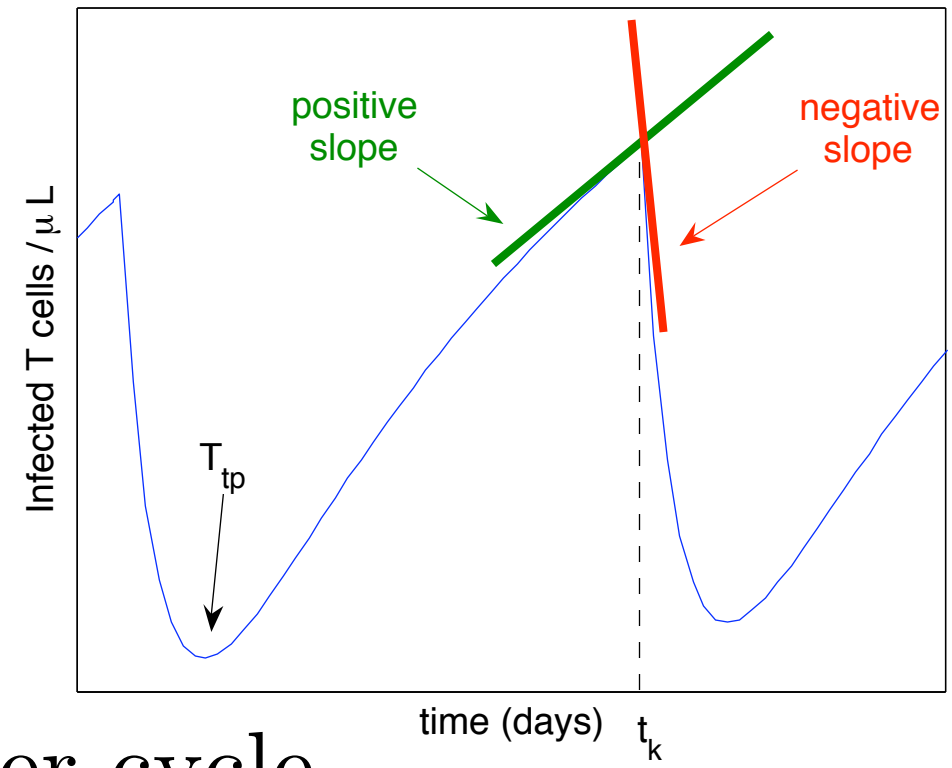
T=infected T cells C=CTLs t_k=vaccination time

Infected T cell minimum

- Easy to show:

$$\frac{dT}{dt}(t_k^+) < \frac{dT}{dt}(t_k^-)$$

$$\frac{dT}{dt} = 0 \quad \text{only once per cycle}$$



- Denote this turning point by (T_{tp}, C_{tp})

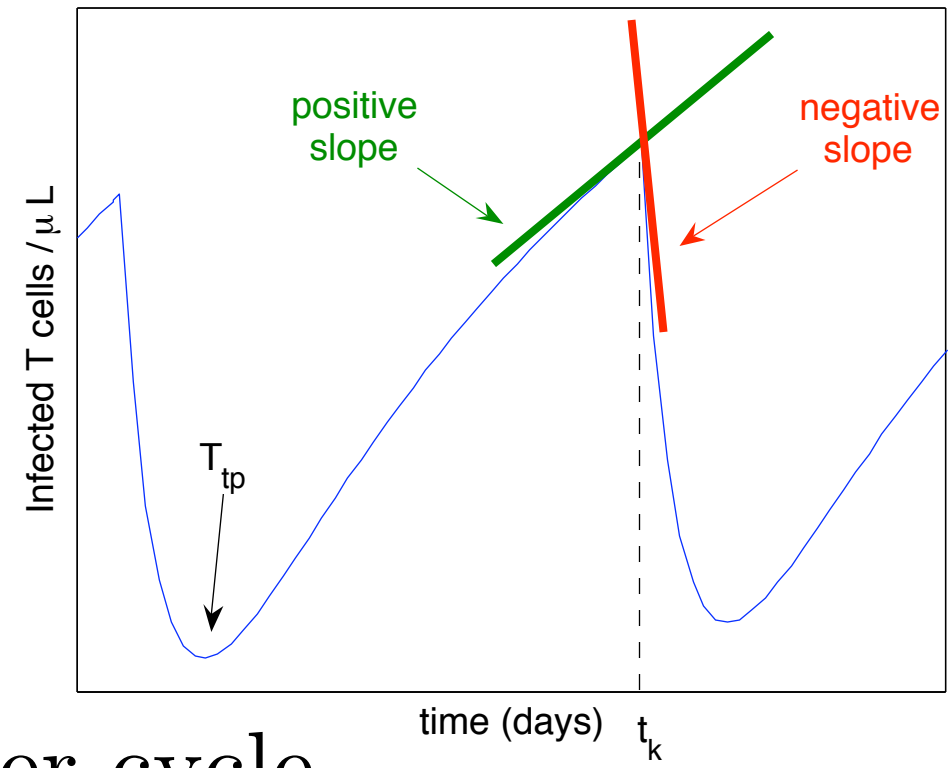
T=infected T cells C=CTLs t_k=vaccination time

Infected T cell minimum

- Easy to show:

$$\frac{dT}{dt}(t_k^+) < \frac{dT}{dt}(t_k^-)$$

$$\frac{dT}{dt} = 0 \quad \text{only once per cycle}$$



- Denote this turning point by (T_{tp}, C_{tp})
- Clearly this turning point is a minimum.

T=infected T cells C=CTLs t_k=vaccination time

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\rm int} = e^{\alpha\tau T_{\rm av} - \delta\tau}$,

T=infected T cells π*=production rate* δ*=death rate* C^i*=vaccine strength* T_{av}*=av # cells*
C=CTLs α*=proliferation rate p=clearance rate* τ*=vaccination period* (T_{tp}, C_{tp})*=T-cell min*

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\rm int} = e^{\alpha\tau T_{\rm av} - \delta\tau}$,

$$\frac{dT}{dt}(T_{\rm tp}, C_{\rm tp}) = \pi - dT_{\rm tp} - pC_{\rm tp}T_{\rm tp} \quad = \quad 0$$

T=infected T cells π*=production rate* δ*=death rate* C^i*=vaccine strength* T_{av}*=av # cells*
C=CTLs α*=proliferation rate p=clearance rate* τ*=vaccination period* (T_{tp}, C_{tp})*=T-cell min*

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\rm int} = e^{\alpha\tau T_{\rm av} - \delta\tau}$,

$$\frac{dT}{dt}(T_{\rm tp}, C_{\rm tp}) = \pi - dT_{\rm tp} - pC_{\rm tp}T_{\rm tp} = 0$$

$$\pi - \left(d + \frac{pC^i T_{\rm int}}{1 - T_{\rm int}}\right) T_{\rm av} < 0$$

T=infected T cells π=production rate δ=death rate C^i=vaccine strength T_{av}=av # cells
C=CTLs α=proliferation rate p=clearance rate τ=vaccination period (T_{tp},C_{tp})=T-cell min

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\mathrm{int}} = e^{\alpha\tau T_{\mathrm{av}} - \delta\tau}$,

$$\begin{aligned}
\frac{dT}{dt}(T_{\mathrm{tp}}, C_{\mathrm{tp}}) = \pi - dT_{\mathrm{tp}} - pC_{\mathrm{tp}}T_{\mathrm{tp}} &= 0 \\
\pi - \left(d + \frac{pC^i T_{\mathrm{int}}}{1 - T_{\mathrm{int}}}\right) T_{\mathrm{av}} &< 0 \\
\pi - \left(d + \frac{pC^i e^{\alpha\tau T_{\mathrm{av}} - \delta\tau}}{1 - e^{\alpha\tau T_{\mathrm{av}} - \delta\tau}}\right) T_{\mathrm{av}} &< 0
\end{aligned}$$

T=infected T cells π=production rate δ=death rate C^i=vaccine strength T_{av}=av # cells
C=CTLs α=proliferation rate p=clearance rate τ=vaccination period (T_{tp}, C_{tp})=T-cell min

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\rm int} = e^{\alpha\tau T_{\rm av} - \delta\tau}$,

$$\begin{aligned}
\frac{dT}{dt}(T_{\rm tp}, C_{\rm tp}) = \pi - dT_{\rm tp} - pC_{\rm tp}T_{\rm tp} &= 0 \\
\pi - \left(d + \frac{pC^i T_{\rm int}}{1 - T_{\rm int}}\right) T_{\rm av} &< 0 \\
\pi - \left(d + \frac{pC^i e^{\alpha\tau T_{\rm av} - \delta\tau}}{1 - e^{\alpha\tau T_{\rm av} - \delta\tau}}\right) T_{\rm av} &< 0
\end{aligned}$$

Thus

T=infected T cells π=production rate δ=death rate C^i=vaccine strength T_{av}=av # cells
C=CTLs α=proliferation rate p=clearance rate τ=vaccination period (T_{tp},C_{tp})=T-cell min

Estimating the vaccination period

Since $T_{tp} < T_{av}$, $C_{tp} > C(\tau^-)$ and $T_{\rm int} = e^{\alpha\tau T_{\rm av} - \delta\tau}$,

$$\begin{aligned}
\frac{dT}{dt}(T_{\rm tp}, C_{\rm tp}) = \pi - dT_{\rm tp} - pC_{\rm tp}T_{\rm tp} &= 0 \\
\pi - \left(d + \frac{pC^i T_{\rm int}}{1 - T_{\rm int}}\right) T_{\rm av} &< 0 \\
\pi - \left(d + \frac{pC^i e^{\alpha\tau T_{\rm av} - \delta\tau}}{1 - e^{\alpha\tau T_{\rm av} - \delta\tau}}\right) T_{\rm av} &< 0
\end{aligned}$$

Thus

$$\tau < \frac{1}{\delta - \alpha T_{\rm av}} \ln\left(1 + \frac{pC^i T_{\rm av}}{\pi - dT_{\rm av}}\right).$$

T=infected T cells π=production rate δ=death rate C^i=vaccine strength T_{av}=av # cells C=CTLs α=proliferation rate p=clearance rate τ=vaccination period (T_{tp},C_{tp})=T-cell min

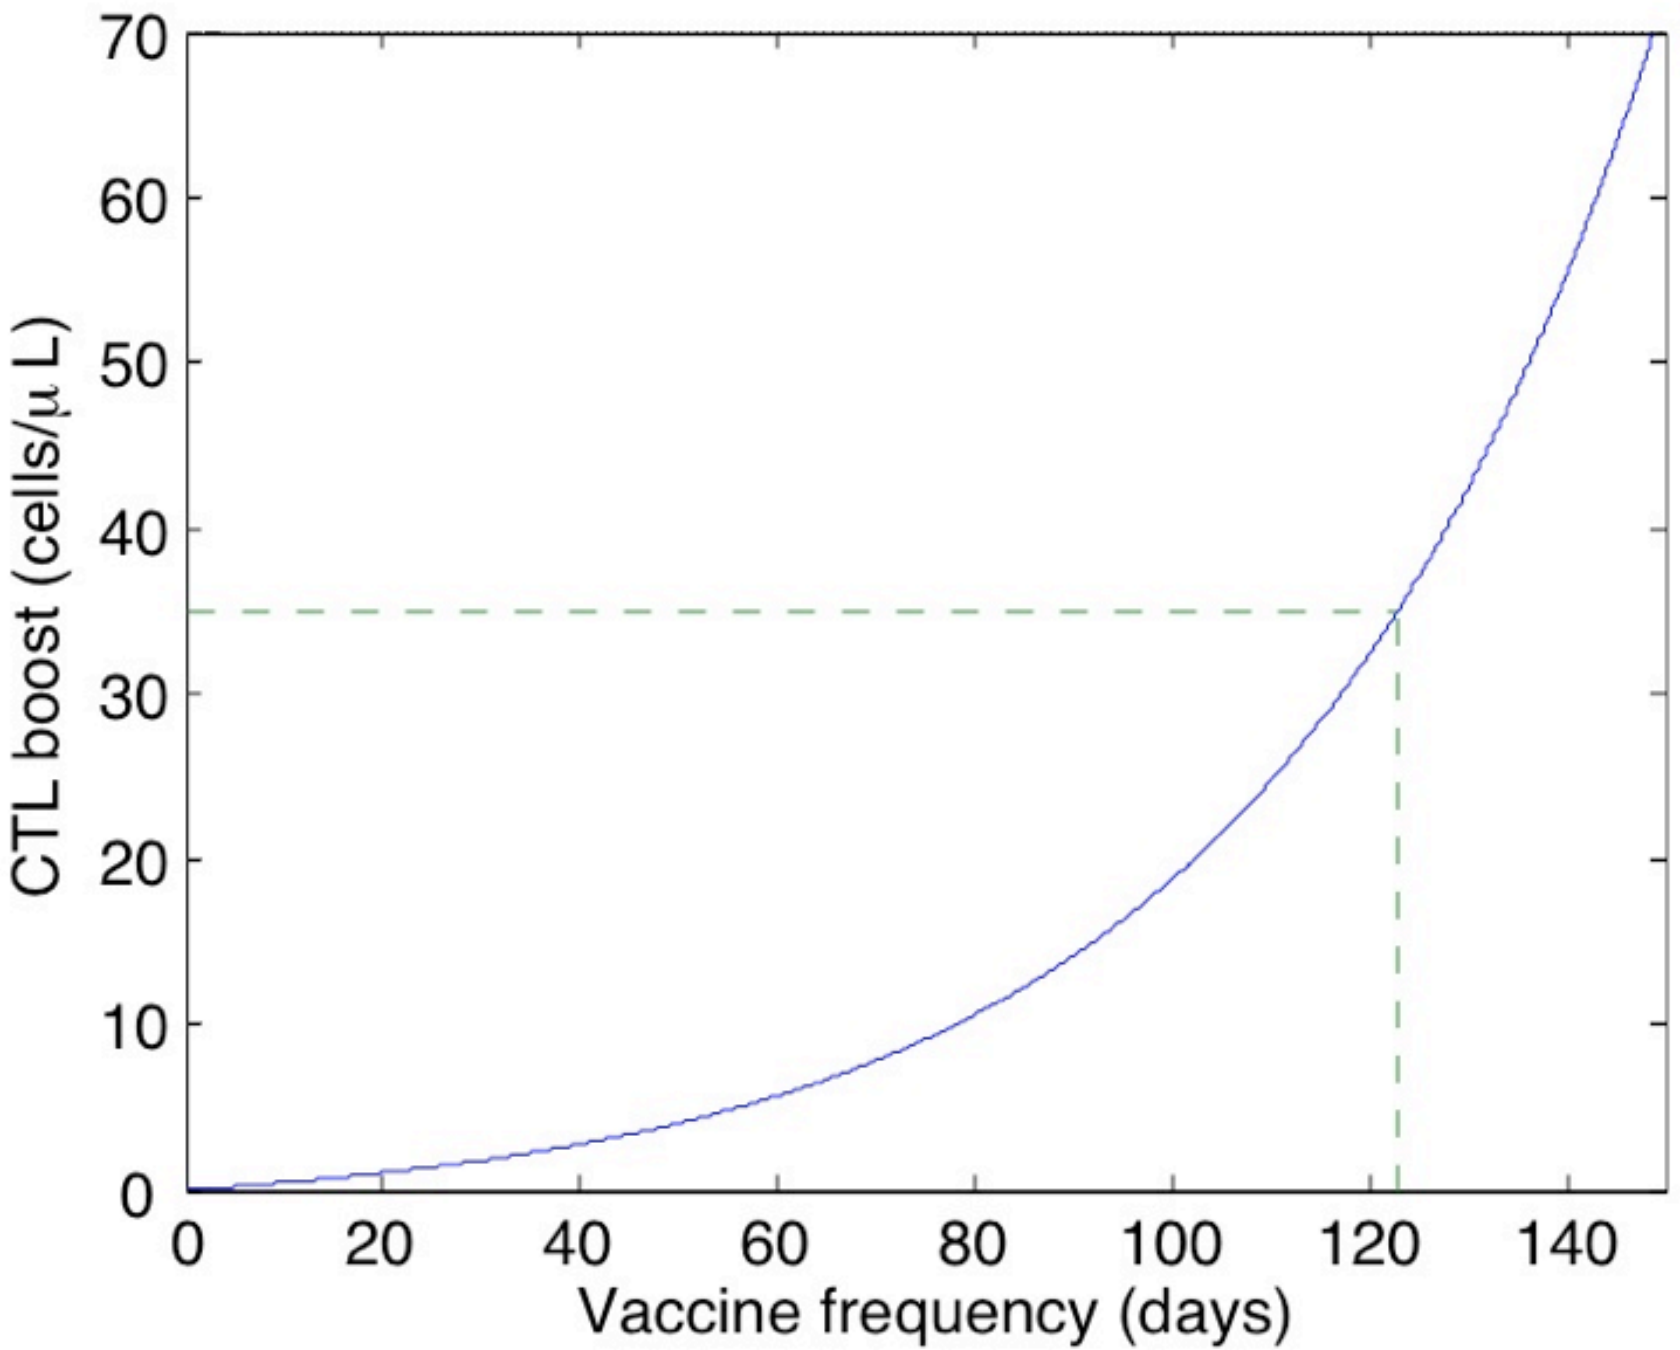
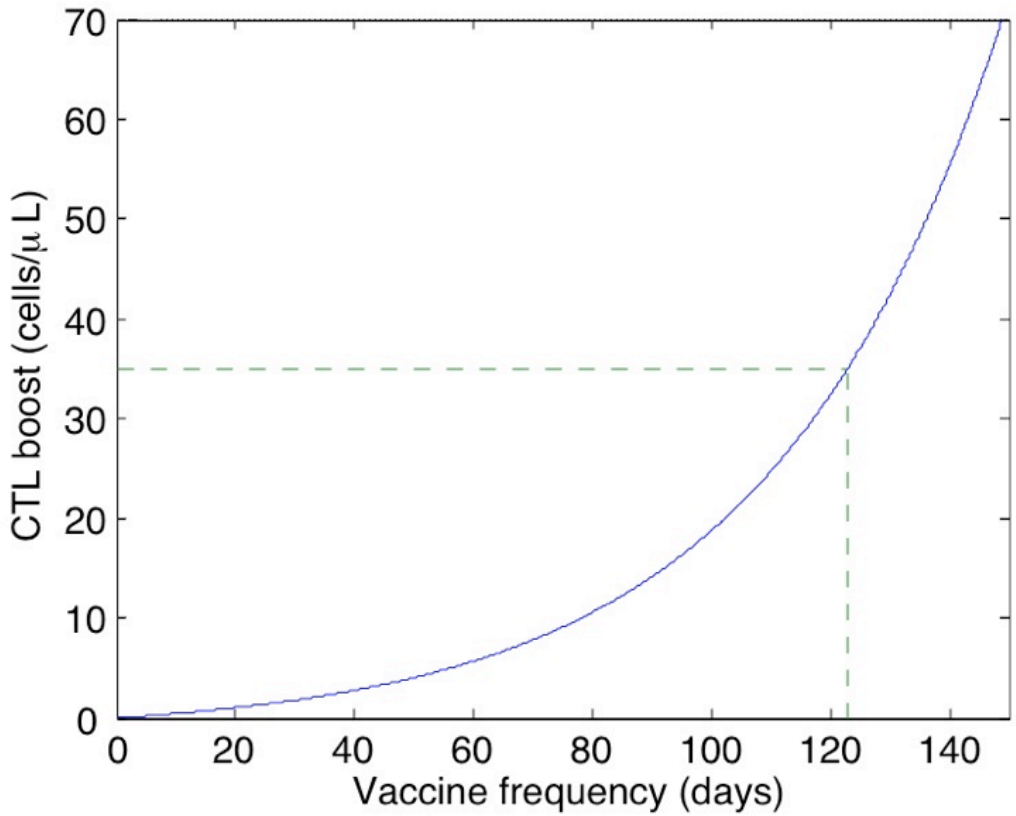
$$\tau < \frac{1}{\delta - \alpha T_{\mathrm{av}}} \ln\left(1 + \frac{pC^i T_{\mathrm{av}}}{\pi - dT_{\mathrm{av}}}\right).$$

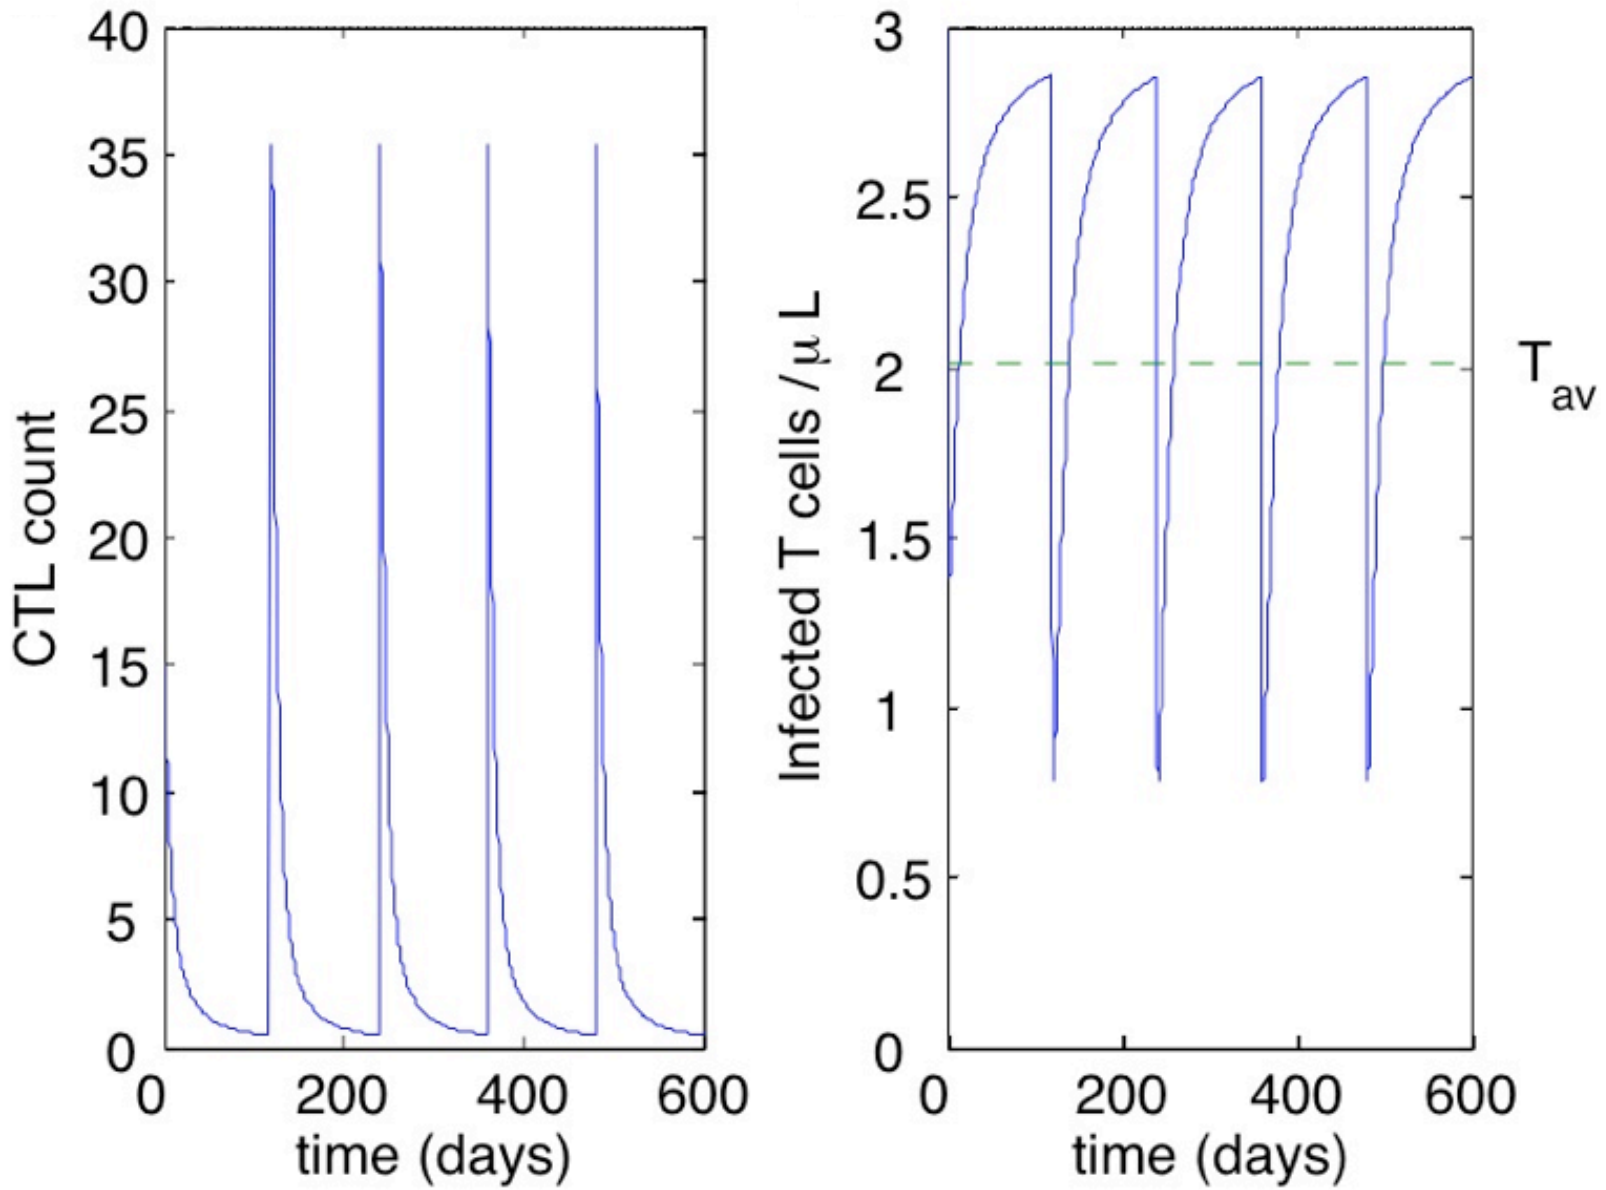


How strong and how often?

A CTL boost of 35 cells μL^{-1} that was applied every 122 days or fewer would ensure the average infected T cell count remained below 2.6 cells μL^{-1}.



C^i = 35 cells μL^{-1}, τ = 120 days

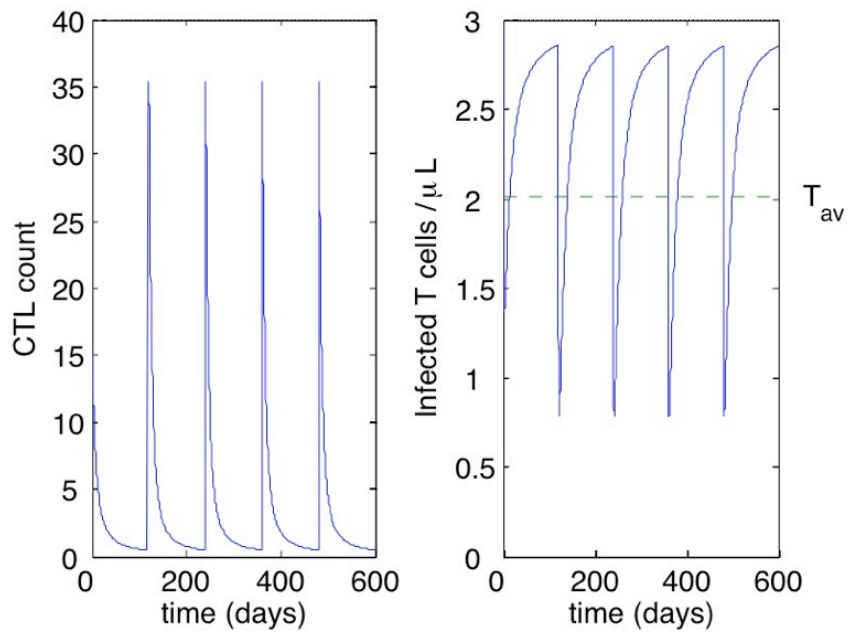


An overestimate

- The inequality is an overestimate

An overestimate

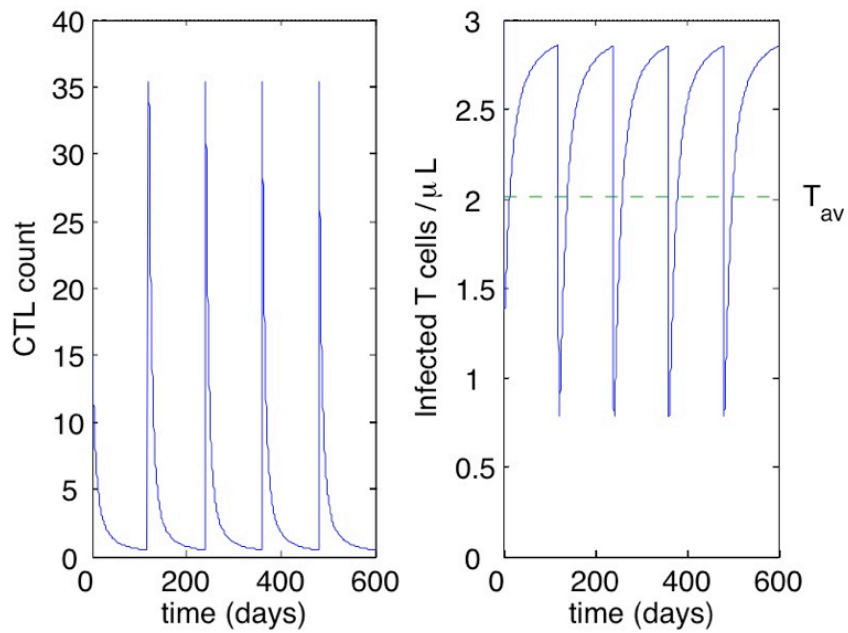
- The inequality is an overestimate
- A CTL boost of 35 cells administered every 120 days produced an actual average of 2.02 cells μL^{-1}



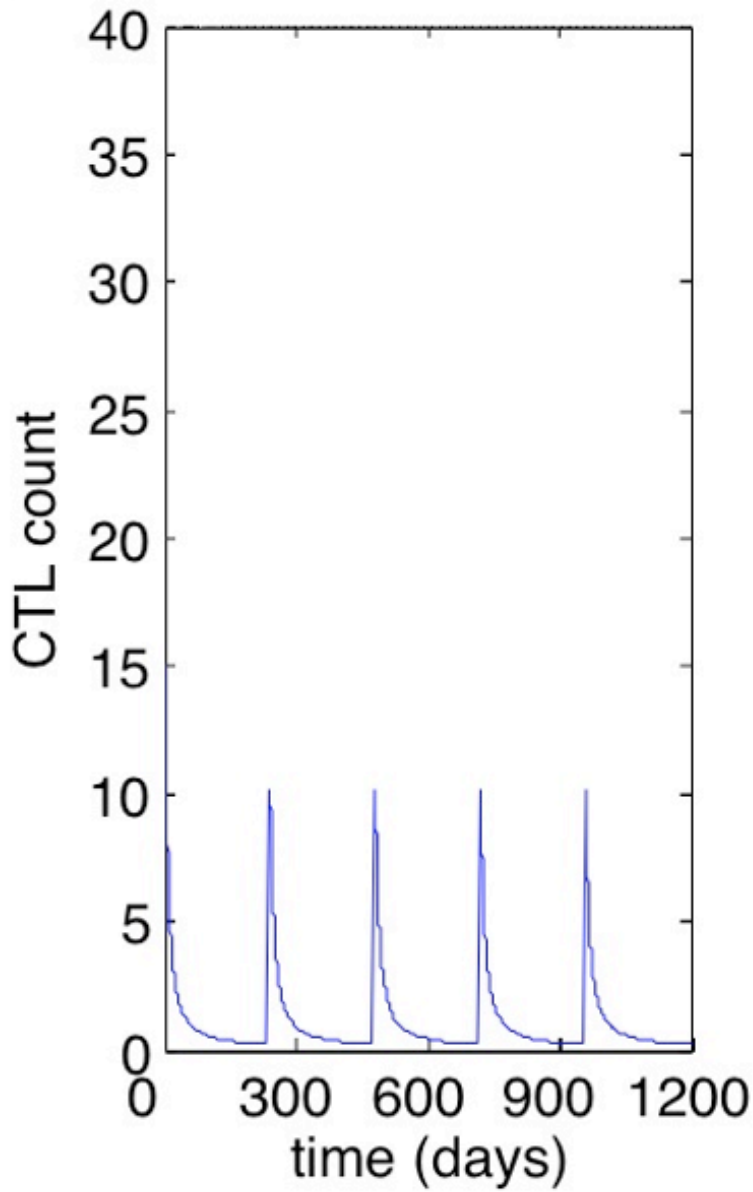
An overestimate

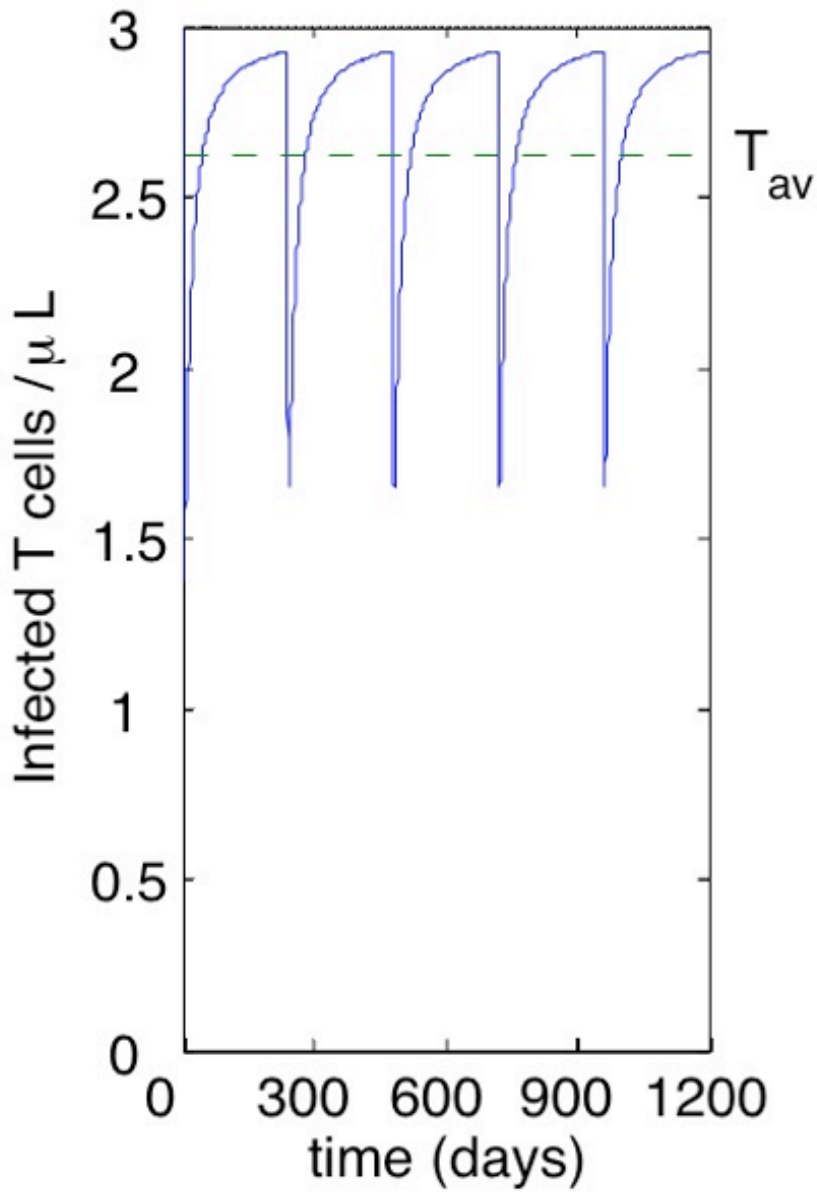
- The inequality is an overestimate
- A CTL boost of 35 cells administered every 120 days produced an actual average of 2.02 cells μL^{-1}

  (better than the desired 2.6 cells μL^{-1}).



C^i = 10 cells μL^{-1}, τ = 240 days



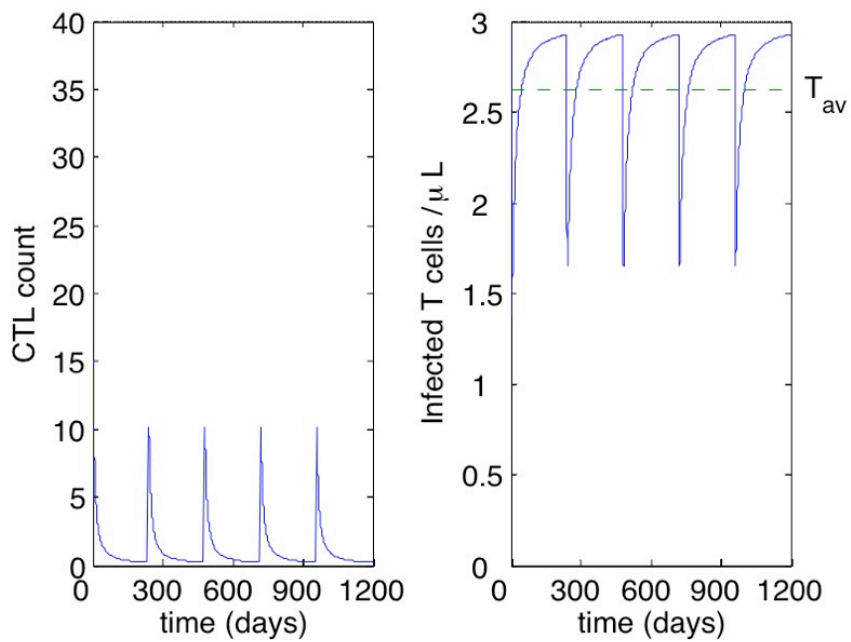


Infrequent vaccination

- Low or infrequent vaccination has minimal effect on the infected T cell counts

Infrequent vaccination

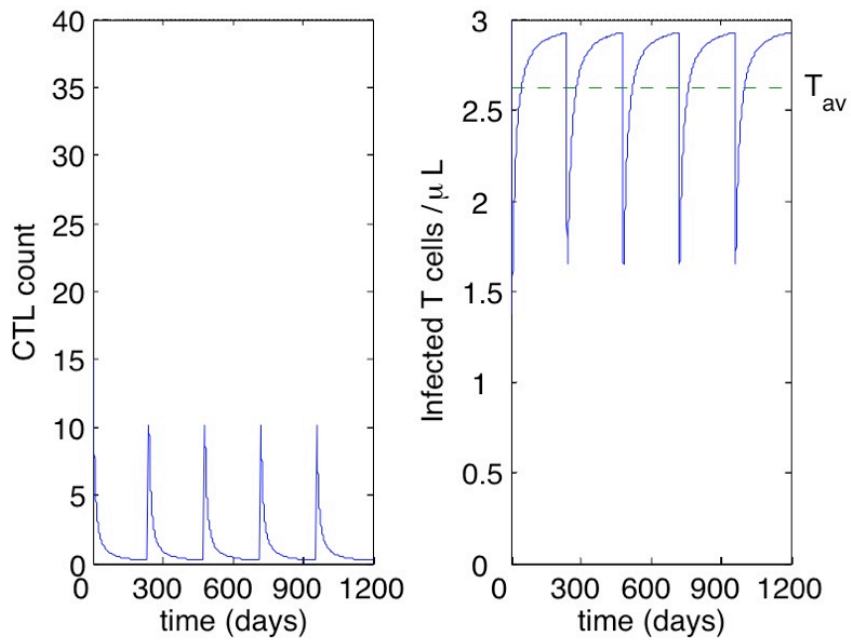
- Low or infrequent vaccination has minimal effect on the infected T cell counts
- A CTL boost of 10 cells administered every 240 days produced an actual average of 2.65 cells μL^{-1}



Infrequent vaccination

- Low or infrequent vaccination has minimal effect on the infected T cell counts
- A CTL boost of 10 cells administered every 240 days produced an actual average of 2.65 cells μL^{-1}

  (worse than the desired 2.6 cells μL^{-1}).



How accurate is the approximation?

- Modelling the change in CTL numbers by an instantaneous change is obviously an approximation

How accurate is the approximation?

- Modelling the change in CTL numbers by an instantaneous change is obviously an approximation
- In reality, CTLs take ~14 days to reach peak values

How accurate is the approximation?

- Estimates are only reasonable during the asymptomatic phase of infection
- Results may be sensitive to parameter variation
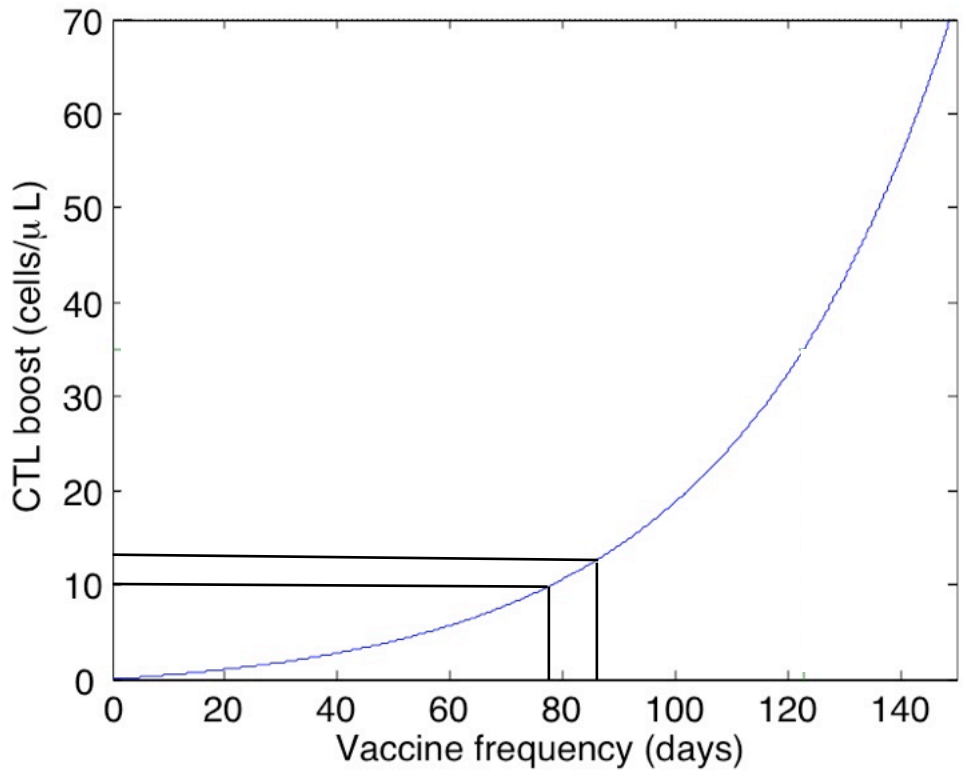
- Impulsive Floquet theory is not easily extendable to higher-order models.

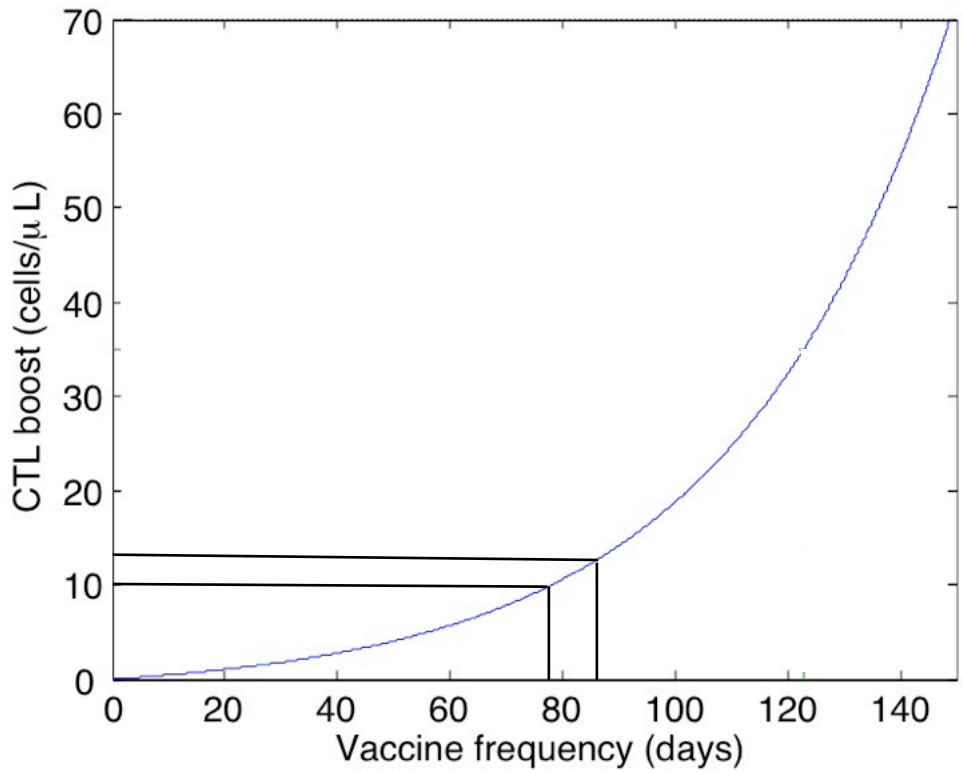
Implications for weak vaccines

- A small increase in the vaccine strength may result in a significantly larger range of possible vaccination intervals when the boost is low



Implications for weak vaccines

- A small increase in the vaccine strength may result in a significantly larger range of possible vaccination intervals when the boost is low
- Thus, CTL vaccines whose strength is too low would be less desirable, even if the frequency could be tolerated.



Attractiveness of such vaccines

- Currently, the only treatment option is antiretroviral drugs

Attractiveness of such vaccines

- Currently, the only treatment option is antiretroviral drugs
- Such drugs have harsh side effects, lead to drug resistance and require frequent daily administration

Attractiveness of such vaccines

- Currently, the only treatment option is antiretroviral drugs
- Such drugs have harsh side effects, lead to drug resistance and require frequent daily administration
- A CTL vaccine would offset the daily pill burden.

Potential drawbacks

- Logistical difficulties in administering regular vaccines to large populations

Potential drawbacks

- Logistical difficulties in administering regular vaccines to large populations
- The consequences of missing a single vaccination are more severe than missing a single drug dose.

Future work

- Adherence to a regular CTL vaccine

Future work

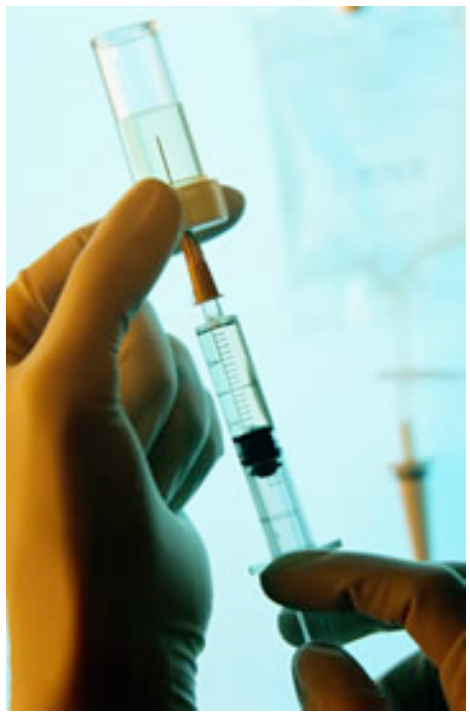
- Adherence to a regular CTL vaccine
- The effects of fluctuations in the vaccination time, even if administered quasi-regularly

Future work

- Adherence to a regular CTL vaccine
- The effects of fluctuations in the vaccination time, even if administered quasi-regularly
- Consequences of vaccine “resistance”.

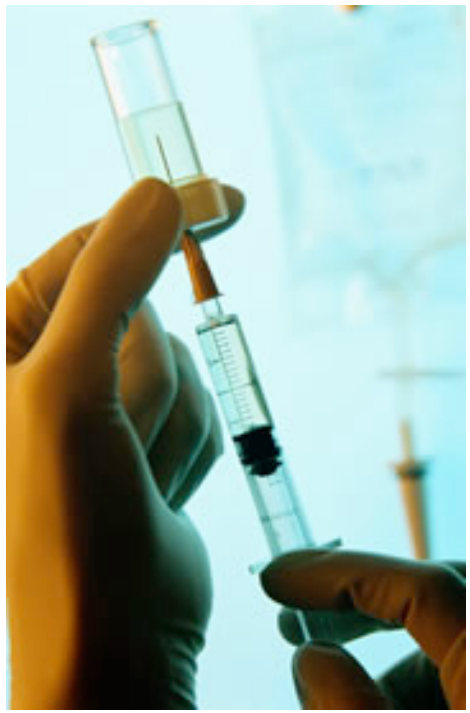
Summary

- A CTL vaccine pulsed at regular intervals can keep the average number of infected $CD4^+$ T cells arbitrarily low, by choosing appropriate vaccination intervals and strength of the vaccine



Summary

- A CTL vaccine pulsed at regular intervals can keep the average number of infected $CD4^+$ T cells arbitrarily low, by choosing appropriate vaccination intervals and strength of the vaccine
- The estimate is overconservative, so this will actually result in a lower average number of infected T cells than theoretically predicted.



Conclusions

- A post-infection CTL vaccine would be highly desirable, assuming perfect patient adherence

Conclusions

- A post-infection CTL vaccine would be highly desirable, assuming perfect patient adherence
- Such a vaccine would offer a realistic alternative to the daily pill burden of antiretroviral drug therapy

Conclusions

- A post-infection CTL vaccine would be highly desirable, assuming perfect patient adherence
- Such a vaccine would offer a realistic alternative to the daily pill burden of antiretroviral drug therapy
- We recommend that such a vaccine should be available for self-administration by patients.
